INFORMATION TO USERS

This manuscript has been reproduced from the microfilm master. UMI films the text directly from the original or copy submitted. Thus, some thesis and dissertation copies are in typewriter face, while others may be from any type of computer printer.

The quality of this reproduction is dependent upon the quality of the copy submitted. Broken or indistinct print, colored or poor quality illustrations and photographs, print bleedthrough, substandard margins, and improper alignment can adversely affect reproduction.

In the unlikely event that the author did not send UMI a complete manuscript and there are missing pages, these will be noted. Also, if unauthorized copyright material had to be removed, a note will indicate the deletion.

Oversize materials (e.g., maps, drawings, charts) are reproduced by sectioning the original, beginning at the upper left-hand corner and continuing from left to right in equal sections with small overlaps. Each original is also photographed in one exposure and is included in reduced form at the back of the book.

Photographs included in the original manuscript have been reproduced xerographically in this copy. Higher quality 6” x 9” black and white photographic prints are available for any photographs or illustrations appearing in this copy for an additional charge. Contact UMI directly to order.

In the name of Allah, Most Gracious, Most Merciful. Read in the name of thy Lord and Cherisher, Who created. Created man from a {leech-like} clot. Read and thy Lord is Most Bountiful. He Who taught {the use of} the pen. Taught man that which he knew not. Nay, but man doth transgress all bounds. In that he looketh upon himself as self-sufficient. Verily, to thy Lord is the return {of all}.

(The Holy Quran, Surah 96)

All praises are for ALLAH subhanahu-wa-ta-Aaala, the Most Compassionate, the Most Merciful. May peace and blessings be upon Prophet Muhammad, and his family. I thank Almighty Allah for giving me the knowledge and patience to complete this work. May He guide me and the whole humanity to the right path (Aameen). I acknowledge the support and facilities provided by the King Fahd University of Petroleum and Minerals for this work.

I would like to express my profound gratitude and appreciation to my thesis committee chairman Dr. Fouad AL-Sunni, for his constant help, guidance and the attention that he devoted throughout the course of this work. He was always kind, understanding and sympathetic to me.

I would like to thank co-chairman Prof. Shahgir Ahmed, whose continuous encouragement can never be forgotten. His valuable suggestions made this work interesting and learning for me.

Thanks are also due to my thesis committee members Prof. Abdul Kebir Boukas and Dr. Moustafa El-Shafei for their interest, cooperation, advice and constructive criticisms.
I also wish to thank the faculty, and the staff members of the Systems Engineering Department for their support, especially to Dr. Abdulbasit Andijani for his moral support and encouragement throughout this work.

Special acknowledgment is due to my friends Mahboob, Abdul Samad, Aleem, Anas, Hasan, Bhatti and to all my friends at KFUPM for their moral support, good wishes and the memorable days we shared together.

Finally, I thank my parents, brothers and Shahina for their love, sacrifices, prayers and understanding. They helped me a lot in achieving my objectives.

Title: Variable Structure Control of Nonlinear Systems
Degree: Master of Science
Major Field: Systems Engineering
Date of Degree: May 1998

Variable Structure Control (VSC) with sliding mode is a special type of control technique that is capable of making a control system robust with respect to system parameter variations and external disturbances. The chattering of the VSC signal can be reduced by several methods. One way is to augment the system with an integrator to isolate the system from the VSC control signal which causes the chatter. In addition, the magnitude of the switching function can be reduced by estimation of the uncertainty. In this work, we designed a Variable Structure Controller for linearizable systems. The concept of augmented plant together with the identification of the uncertainty through an observer has been used to design a controller for uncertain nonlinear systems which do not necessarily meet the matching conditions. The scheme is also shown to reduce the chattering. The simulation and the comparison studies reported in this thesis suggest the usefulness of our scheme.

Chapter 1

Introduction

1.1 Motivation

In this chapter, a brief look at the motivation behind the research in the field of nonlinear systems analysis and design is taken. The motivation of using the feedback linearization technique and designing the variable structure controller for the nonlinear system is also established. Finally, the organization of the thesis is presented.

In the past, the computational difficulty associated with nonlinear control analysis and design has limited the application of nonlinear control methods. This is, perhaps due to the complex behavior of nonlinear systems which can display many, often undesirable phenomena, such as limit cycle, chaos phenomena etc. Besides, nonlinear systems are described by nonlinear differential equations which generally cannot be solved.

In the past, feedback control systems were restricted to linear systems or systems that can be linearized by conventional linear methods, such as the traditional lin-
Linearization process which expands the nonlinear differential state equations into a Taylor series about an operating point. Although, linear control methods perform well over a small range of operation, they are impractical to physical systems which are mostly nonlinear.

Recently, as the advent of powerful microprocessors improved our computational ability, many researchers and designer renewed their interest in the development and application of nonlinear control methodologies. Nowadays, tools for analyzing and designing nonlinear control systems are available, such as the describing function approach, the phase plane method and Lyapunov's methods, and adaptive control. In spite of these methods, that have been proposed, our understanding of the behavior of nonlinear systems is still far from complete, and the linearization technique is still of great interest. Unfortunately, the available methods for linearization of nonlinear systems such as approximate linearization, and pseudolinearization are based on approximations of the dynamics.

Recent developments in the theory of geometric nonlinear control provide powerful methods for control design of nonlinear systems. The feedback linearization scheme is a powerful method as it is based on exact cancellation of the nonlinearities present in the system. The feedback linearization approach requires a perfect model of the system in order to achieve linearization of the closed loop system.

However, for many real systems, there often exist inevitable uncertainties in their constructed models. In addition, there exists uncertainty in the parameters that are not exactly known or are difficult to estimate. Therefore, the design of a robust controller that deals with uncertainties in the parameters of a nonlinear system is very important.
Variable Structure Control (VSC) with sliding mode is capable of making a control system robust with respect to system parameter variations and external disturbances. In addition, the technique provides an easy way to design the control law for a plant, linear or Nonlinear.

1.2 Proposed Work

- We propose the concept of Plant Augmentation to the Linearizable Systems.

- Both systems with disturbances and systems with parameter uncertainties will be considered.

- We propose to investigate the problem of inaccessible states for Nonlinear Systems. To this end, we use the observer designed by Solsona et al. [36] for the Nonlinear Systems to estimate the states of the Nonlinear System. The estimates of the states are then used for the linearization of the plant.

- Simulations will be performed to illustrate the proposed work and to compare our schemes with some existing schemes.

1.3 Organization of the thesis

In Chapter 2, the literature survey related to this thesis is presented. In Chapter 3, the concepts of feedback linearization and variable structure control theory are discussed. The design of variable structure controller is also discussed. In Chapter 4, a detailed discussion of the plant augmentation method is carried out. Firstly, a linear plant without uncertainties is dealt and in the later stage, the technique
is extended to linearizable systems with parameter uncertainties and external disturbances. In the latter part, the problem of inaccessible states for the nonlinear systems is also dealt with. In Chapter 5, the simulation results are discussed to illustrate the proposed work. In Chapter 6, the contributions and conclusions of this work are presented with some future research directions.
Chapter 2

Literature Review

A survey of the literature on feedback linearization and variable structure systems theory is presented in this chapter.

Significant research effort has been extended in nonlinear systems linearization during the past decade. This explains the appearance of a number of papers about feedback linearization in the control literature.

Krener [28] solved the problem in which nonlinear systems can be transformed into linear systems, using only a change of variables [41]. Su [54] provided the necessary and sufficient conditions to guarantee the existence of a feedback linearization and mappings to achieve global linearization of a nonlinear system for the single-input single-output case in which a nonlinear system is transformed to a linear system in the controllability canonical form.

Su et al. [30] provided the necessary and sufficient conditions for the existence of a local and global transformation and state feedback linearization for the multi-input multi-output case.

There are different transformation techniques available for linearization of nonlinear
systems. These transformation schemes are basically used to transform nonlinear systems into the controllability canonical form. Recently, a transformation into generalized controller canonical forms for nonlinear dynamics is proposed in Fliess [18]. Under such transformation, nonlinear dynamics can be exactly linearized via dynamic feedback.

The theory of feedback linearization is now well developed and understood [6, 7 and 8]. Slotine [52] has given a complete discussion of this theory and its drawbacks for SISO as well as MIMO Nonlinear Systems. Conditions under which nonlinear systems can be linearized have also been discussed.

To deal with uncertain nonlinear systems, two main approaches have been proposed: adaptive control approach and Lyapunov-based control approach. If the uncertainties appear strictly as uncertain parameters, adaptive control techniques can be used. In the Lyapunov-based control approach, a Lyapunov function is constructed based on which a state feedback control is synthesized using the bounds on the uncertainties.

Petersen [45] discussed the importance of the matching conditions in the stabilization of uncertain systems.

Calvet et al. [9] proposed the design of a stabilizing controller for a nonlinear system in the presence of parametric uncertainty. The proposed design does not necessarily require structure matching conditions between the real plant and the nominal model of the plant. Their robust control design is based on the second method of Lyapunov where algebraic Riccati equations need to be solved.
Chou et al. [10] proposed a design of robust stabilizing controllers for uncertain nonlinear systems. Two categories of uncertainties, the uncertain parameters and the structured uncertainties were considered. A feedforward-like control design was used to achieve robust stability of the system with matched uncertainties, and a parameter diffeomorphism was presented as a high gain control technique to robustify the cancellation of unmatched uncertainty. A simple parameter can be adjusted on-line to suppress the influences of uncertainties on the closed-loop system.

Schoenwald et al. [48] proposed a method for robust stabilization of the uncertain nonlinear system exhibiting parametric uncertainty. A Taylor series of the system about the nominal parameter vector coupled with a feedback linearizing control law yields a linear system plus nonlinear perturbations about the nominal parameters. Via a structure matching condition, a Lyapunov based control law was shown to stabilize the full system. But the drawback to this approach is that the linearizing coordinate transformation depends on the uncertainty, thus it is unknown.

Kwanghee et al. [39], presented a model reference adaptive control scheme for nonlinear system in a pure-feedback canonical form with unknown parameters. They restricted their study to a class of "well structured" nonlinear systems called pure-feedback systems. But under some mild assumptions the design can also be applied to a more general class of nonlinear plants.

Etchechoury et al. [36] discussed the stability of nonlinear plants that include an observer for their feedback linearization. They analysed the situation for a class of nonlinear systems and a class of observers and set the proper sufficient condition that makes possible the stabilization of the whole system: the plant plus the observer.
A number of practical applications using exact feedback linearization have been reported in the literature. These include: aerospace engineering [19, 20], robot manipulators [21, 22], power systems [37], chemical engineering [8], stepper motors [62] and power converters [49].

An excellent survey of feedback linearization and other linearization methods for nonlinear systems have been discussed in [15].

The design of a robust controller that deals with uncertainties of a nonlinear system is an important subject [22]. And one such robust controller can be designed using the Variable Structure Control theory.

The theory of Variable Structure Systems was first proposed and studied in the early 1950s by Soviet researchers [29, 30, 31, 32, 33 and 34]. VSC is capable of making a control system very robust with respect to system parametric uncertainties and external disturbances [35, 36]. But the main concern when using the VSC technique is to avoid the excessive chatter. In the steady-state, chattering appears as a sustained oscillation around the desired equilibrium point and may excite unmodelled high-frequency dynamics of the system which may jeopardize system stability. Therefore, it is desirable to seek effective methods of suppressing the chatter [37, 38].

Slotine et al. [35, 39] suggested a solution to the problem of chattering by smoothing out the control discontinuity in a thin boundary layer neighboring the switching surface. They replaced the signum term in the expression of the control law \( u \) by \( s(x)/(\lambda_{n-1})\epsilon \), where \( \epsilon \) is the boundary layer width and \( \lambda_{n-1} \) is the \((n-1)^{th}\) coefficient of the switching surface. The introduction of a boundary layer around the switching surface leads to an explicit trade-off between tracking precision and ro-
bustness to unmodelled high frequency dynamics while allowing avoidance of control chatter.

Ambrosino et al. [19], also suggested a solution for the chattering problem based on the same lines of slotine and sastry. They replaced the discontinuous sign function by a continuous function of the form \( \frac{s(x)}{|s(x)| + \delta} \), where \( \delta \) is a positive constant which makes the control \( u(x) \) continuous. But there is no systematic method of choosing the \( \delta \).

Burton et al. [7] extended the same solution for multivariable case in which the smoothing function is of the form \( \frac{s_i(x)}{|s_i(x)| + \delta_i} \), \( i = 1, 2, \ldots, m \).

Coetsee et al. [51] discussed how the tracking performance can be further improved using the sliding control and online parameter estimation techniques. The adaptation scheme fully exploits the closed-loop dynamic structure created by the sliding controller and the boundary layer concept. The designer can progressively refine controller tracking performance by identifying the most significant parameter errors and sequentially extending adaptation to them.

Espana et al. [35] proposed a method which allows the designer to simultaneously satisfy the conflicting requirements of short sliding plane reaching time and transient behavior degradation due to the effect of chattering. A switching zone about the switching surface is created such that the state feedback switching parameters, outside the switching zone, are replaced inside the switching zone by switching parameters which make \( s(x) = 0 \). The strategy is illustrated with a microprocessor-based design for the control of a d.c. motor. The main drawback of this work is that they did not take parameter variations and external disturbances into consideration.

Olgac and Chang [43] proposed a strategy to eliminate the control chattering. They
used the constant rate reaching law until the first crossing of the sliding plane and then applied the proportional rate reaching law just after the first crossing of the sliding plane. This control will maintain the sliding of the state on $s(x) = 0$. As a result no control chatter appears on the sliding plane. But the disadvantage of this strategy is that only small ranges of parameter variations are tolerable.

Chang et al. [16] presented a new adaptive chattering alleviation algorithm. The adaptive control algorithm consists of two phases. In phase one, the time required to reach the switching surface is minimized. In phase two, they alleviate the chattering about the switching surface in the sliding mode. The automatic switching between these two phases is based on a recursive prediction procedure performed at each step. But this work doesn't deal with the effect of external disturbances.

Young et al. [59] proposed two different concepts for chattering reduction in sliding mode control. They are Boundary Layer Equivalent Control and Frequency Shaping of Discontinuous control. In the first method, the normal components of the sliding manifold are made continuous which means there is no chattering. In the second method, filtering techniques are used to acquire the disturbance rejection property in finite time with continuous or desirably smooth control inputs.

Zaremba [61] used the idea of hierarchical VSC with on-line iterative tuning of sliding hyperplanes and control function switching terms. The algorithm is based on defining certain local performance indices instead of a global one and is shown to improve the response of the system considerably.

AL-Sunni et al. [1, 2] proposed a new Hybrid scheme employing both adaptive and fuzzy logic schemes to smooth out the chattering phenomenon and simultaneously increase the speed of the system response. The adaptive part provides the
appropriate hyperplane slopes to maximize the system performance and the gain is adjusted depending upon the error and allowable chattering in the system. The fuzzy part along with the self organizing gain effectively reduces chattering in the control signal. The simulation results show that the hybrid scheme is very effective in reducing both magnitude of the control and chattering phenomenon. One way of reducing the steady-state error for systems represented in state space is by inserting an integrator in the feedforward path between the error comparator and the plant [42]. This is known as augmented error approach.

Billing et al. [3] proposed the insertion of a low pass filter ahead of the plant to smooth out the VSC output signal. Filtering methods for suppressing chattering are proposed by in [5, 6, 7].
Chapter 3

Overview of Feedback
Linearization and Variable Structure Control Theory

In this Chapter, the fundamental concepts of feedback linearization and variable structure control theory and various properties of VSC are dealt with in detail.

3.1 Feedback Linearization

The input-state feedback linearization principle is described in this section. Feedback Linearization is the use of coordinate transformation and state feedback to algebraically transform a nonlinear system to a linear one. Once the nonlinear system has been suitably transformed, quite possibly in another coordinate system, the resulting linearized system can be controlled through additional state feedback using
well-established linear control methodologies. Consequently, feedback linearization has been an attractive control design method for highly nonlinear systems.

There are two forms of feedback linearization. They are input-state feedback linearization and input-output feedback linearization. This thesis is concerned only with the input-state feedback linearization.

Feedback Linearization relies on transforming the system's differential equations into the controllable canonical form [29] and then introducing a linearizing feedback [60]. A system is said to be in a controllable canonical form if its dynamics are given by:

\[
\frac{d^n x}{dt^n} = f(x) + g(x)u
\]  

where \( u \) is the scalar control input, and \( x \in \mathbb{R}^n \) is the state vector:

\[
x = [x \quad \frac{dx}{dt} \quad \ldots \quad \frac{d^{n-1}x}{dt^{n-1}}]'\]  

(3.1)

and \( n \) is the number of states, and the prime sign stands for transpose. In state space representation this can be written in the following form:

\[
\frac{dx_1}{dt} = x_2
\]

\[
\vdots
\]

\[
\frac{dx_n}{dt} = f(x) + g(x)u
\]  

(3.3)
In a matrix representation, this can be written as:

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n
\end{bmatrix} = 
\begin{bmatrix}
x_2 \\
x_3 \\
\vdots \\
f(x)
\end{bmatrix} + 
\begin{bmatrix}
0 \\
0 \\
\vdots \\
g(x)
\end{bmatrix} u
\]

(3.4)

### 3.1.1 Mathematical Tools

In this section some mathematical results from differential geometry on which feedback linearization is based are discussed.

A vector function \( f : \mathbb{R}^n \rightarrow \mathbb{R}^n \) is a smooth vector field if it has continuous partial derivatives of any required order.

If \( h(x) \) is a smooth scalar function of the state \( x \), the gradient of \( h \) is denoted by \( \nabla h \).

\[
\nabla h = \frac{\partial h}{\partial x}
\]

The gradient is represented by a row-vector of elements \((\nabla h)_i = \partial h / \partial x_i\).

Similarly, given a vector field \( f(x) \), the Jacobian of \( f \) is denoted by \( \nabla f \).

\[
\nabla f = \frac{\partial f}{\partial x}
\]

whose elements are:

\[
(\nabla f)_{ij} = \frac{\partial f_i}{\partial x_j}
\]
3.1.2 Lie Derivatives and Lie Brackets

Let \( h : \mathbb{R}^n \rightarrow \mathbb{R}^n \) be a smooth scalar function, and \( f : \mathbb{R}^n \rightarrow \mathbb{R}^n \) be a smooth vector field on \( \mathbb{R}^n \), then the Lie derivative of \( h \) with respect to \( f \) is a scalar function defined by \( L_f h = \nabla h f \), which is directional derivative of \( h \) along the direction of the vector \( f \). A recursive definition can be assigned to higher order Lie derivatives as follows:

\[
L_f^0 h = h
\]

\[
L_f^i h = L_f(L_f^{i-1} h) = \nabla(L_f^{i-1} h)f \quad \text{for} \quad i = 1, 2, \cdots.
\]

Similarly, if \( f \& g \) are two vector fields on \( \mathbb{R}^n \), the Lie bracket of \( f \& g \) is a third vector field defined by:

\[
ad_{fg} = [f, g] = \nabla g f - \nabla f g
\]

where \( ad \) stands for adjoint.

Diffeomorphism

A diffeomorphism can be used to transform a nonlinear system into another nonlinear system in terms of a new set of states.

A function \( \phi : \mathbb{R}^n \rightarrow \mathbb{R}^n \), defined in a region \( \Omega \) is called a diffeomorphism if it is smooth, and if its inverse \( \phi^{-1} \) exists and is smooth.

If the Jacobian matrix \( \nabla \phi \) is non-singular at a point \( x = x_0 \) of \( \Omega \), then \( \phi(x) \) defines a local diffeomorphism in a subregion of \( \Omega \). If the region \( \Omega \) is the whole space \( \mathbb{R}^n \), then \( \phi(x) \) is called a global diffeomorphism.
Frobenius Theorem

A linear independent set of vector fields $f_1, f_2, \cdots, f_m$ is said to be involutive if the Lie bracket of $f_i$ and $f_j$ can be expressed as a linear combination of $f_i$, $i = 1, \cdots, m$. In other words, a linearly independent set of vector fields $f_1, f_2, \cdots, f_m$ is said to be involutive if and only if there are scalar functions $\alpha_{ijk}(x)$ such that

$$[f_i, f_j](x) = \sum_{k=1}^{m} \alpha_{ijk}(x) f_k(x) \quad \forall i, j$$  \hspace{1cm} (3.5)

A linearly independent set of vector fields $f_1, f_2, \cdots, f_m$ on $\mathbb{R}^n$ is said to be completely integrable if and only if there exists $n - m$ scalar functions $h_1(x), h_2(x), \cdots, h_m(x)$ satisfying the system of partial differential equations:

$$\nabla h_i f_j = 0$$

where $1 \leq i \leq n - m$, $1 \leq j \leq m$, and the gradients $\nabla h_i$ are linearly independent.

Frobenius theorem states that the set of vector fields $f, g$ is completely integrable if and only if it is involutive.

3.1.3 Definition of Input-State Linearization

A single-input nonlinear system of the form,

$$\dot{x} = f(x) + g(x)u$$
with $f(x)$ and $g(x)$ being smooth vector fields on $\mathbb{R}^n$, is said to be input-state linearizable if there exists a region $\Omega$ in $\mathbb{R}^n$, a diffeomorphism $\phi : \Omega \rightarrow \mathbb{R}^n$, and a nonlinear feedback control law,

$$ u = \alpha(x) + \beta(x) v $$

such that the new state variables $z = \phi(x)$ and the new input $v$ satisfy a linear time-invariant relation,

$$ \dot{z} = Az + bv $$

where

$$ A = \begin{bmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 1 \\
0 & 0 & 0 & \cdots & 0
\end{bmatrix} \quad \text{and} \quad b = \begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
1
\end{bmatrix} \quad (3.6) $$

The new state $z$ is called the *linearizing state* and the control law is called the

---

**Figure 3.1: Input-State Linearization**
3.1.4 Conditions for Input-State Linearization

The nonlinear system is input-state linearizable if and only if:

1. The set of vector fields \( \{ g, ad_{f}g, \ldots ad_{f}^{n-1}g \} \) are linearly independent in \( \Omega \).

   Checking this condition, it interprets the controllability condition for the nonlinear system. i.e.
   \[
   \text{rank}[g, ad_{f}g, \ldots ad_{f}^{n-1}g] = n
   \]

   For linear systems, the vector fields \( \{ g, ad_{f}g, \ldots ad_{f}^{n-1}g \} \) becomes \( [b, Ab, \ldots A^{n-1}b] \)
   and therefore their independence is equivalent to the invertibility of the familiar linear controllability matrix.

2. The set \( \{ g, ad_{f}g, \ldots ad_{f}^{n-2}g \} \) is involutive in \( \Omega \).

   Involutivity means that if one forms the Lie bracket of any pairs of vector fields from
   the set \( \{ f_1, f_2, \ldots f_m \} \), then the resulting vector field can be expressed as a linear
   combination of the original set of vector fields.

   If the above two conditions hold, then there exists a nonsingular state transformation, \( T(x) \), defined from \( \Omega \rightarrow \mathbb{R}^n \), which transforms the nonlinear system into the
   controllable canonical form and a nonlinear feedback control law \( u \) which cancels
   the nonlinear terms in the \( n^{th} \) partial differential equation.

   The input-state feedback linearization method solves the problem of designing the
   control input \( u \) in order to cancel the nonlinear terms into two steps. First, the
   nonlinear dynamics is transformed into the controllable canonical form by finding a
   state transformation \( T(x) \). Then, a linearizing input is found in order to transform
the nonlinear system into a linear one.

Example

Consider the control of the mechanism of a single link joint flexible manipulator. Its equations of motion can be easily derived as [52]

\[ I\ddot{q}_1 + MgL\sin q_1 + k(q_1 - q_2) = 0 \]

\[ J\ddot{q}_2 - k(q_1 - q_2) = u \]

First, let us put the system's dynamics in a state-space representation. Choosing the state vector as

\[ x = [q_1 \quad \dot{q}_1 \quad q_2 \quad \dot{q}_2]^T \]

the corresponding vector fields \( f \) and \( g \) can be written as

\[ f = [x_2 \quad -\frac{MgL}{I}\sin x_1 - \frac{k}{I}(x_1 - x_3) \quad x_4 \quad \frac{k}{J}(x_1 - x_3)]^T \]

\[ g = [0 \quad 0 \quad 0 \quad \frac{1}{J}]^T \]
Second, let us check the "controllability" and involutivity conditions. The "controllability" matrix is obtained by simple computation as

\[
\begin{bmatrix}
g & ad_{fg} & ad^2_{fg} & ad^3_{fg} \\
0 & 0 & 0 & -\frac{k}{IJ} \\
0 & 0 & \frac{k}{IJ} & 0 \\
0 & -\frac{1}{J} & 0 & \frac{k}{J^2} \\
\frac{1}{J} & 0 & -\frac{k}{J^2} & 0 \\
\end{bmatrix}
\]

(3.7)

It has rank 4 for \( k > 0, IJ < \infty \). Furthermore since the vector fields \( \{ g, ad_{fg}, ad^2_{fg} \} \) are constant, they form an involutive set. Therefore, the system is input-state linearizable.

### 3.1.5 Limitations of Feedback Linearization

The feedback linearization based on transforming nonlinear systems into a linear one by using state feedback has been successfully applied to a number of practical control problems. It has been used as a controller design tool. However, this method has a number of important limitations:

1. It is only applied for feedback linearizable nonlinear systems which satisfy the "controllability" and involutivity conditions.

2. It is an off-line method.

3. Input-state feedback linearization, in general, is not valid in the whole space.

4. Exact dynamics of the nonlinear plant must be known.
5. The partial differential equations defining the input-state transformation are solved analytically which is not systematic.

### 3.2 Variable Structure Control

Variable Structure Control is a viable high-speed switching feedback control in which the control is allowed to change its structure, i.e. to switch from one element to another of a set of possible continuous functions of the state variables. VSC utilizes a high-speed switching control law to drive the nonlinear plant's state trajectory onto a specified and user-chosen surface in the state space, called the sliding or switching surface to maintain the plant's state trajectory on that surface for all subsequent time [25].

As the name variable structure control suggests the structure of the control is altered along the switching surfaces in state space with the result that certain desirable properties are achieved. Once the system state reaches the switching plane, the system response thereafter depends only on the gradients of the switching planes and remains insensitive to a class of disturbances and parameter variations [12]. The most distinguished feature of VSC is its ability to result in a very robust control system.

Variable structure control with sliding mode was first proposed in the early 1950s by soviet researchers. In their work, the plant considered was a linear second-order system modelled in canonical form. Later on, VSC has developed into a general design method being examined for a wide spectrum of system types including Nonlinear Systems, MIMO systems, discrete-time models, large-scale and infinite-dimensional systems and stochastic systems. To illustrate the basic philosophy of
the VSC system approach, consider a second-order system [26],

\[
\begin{align*}
\dot{x} &= y \\
\dot{y} &= 2y - x + u \\
u &= -\psi x
\end{align*}
\]  

(3.8)

where

\[
\psi = \begin{cases} 
4, & S(x, y) > 0 \\
-4, & S(x, y) < 0 
\end{cases}
\]  

(3.9)

and

\[
S(x, y) = x\sigma, \sigma = 0.5x + y.
\]  

(3.10)

A block diagram of the system is shown in Figure 3.2. The variable \(S(x, y)\) is the product of two functions, \(x = 0\) and \(\sigma = 0.5x + y = 0\). The functions describe lines dividing the phase plane into regions where \(S(x, y)\) has different sign. The lines \(x = 0\) and \(\sigma = 0.5x + y = 0\) are often called switching lines and the product of the two, \(S(x, y)\), is called a switching function. The set of points in the phase plane where \(S(x, y) = 0\) is known as the switching surface.

From the system model, we can see that, the feedback gain \(\psi\) switches according to the sign of \(S(x, y)\) and hence the performance of the system is defined into several regions of the phase plane by two different mathematical models as shown in Figure 3.3;

In region I, where \(S(x, y) = x\sigma > 0\), model is

\[
\dot{x} = y
\]
Figure 3.2: A simple VSC example. (a) System Model. (b) Regions defined by the Switching logic.
\[ \dot{y} = 2y - x - 4x = 2y - 5x \]

In region II, where \( S(x, y) = x \sigma < 0 \), model is

\[ \dot{x} = y \]

\[ \dot{y} = 2y - x + 4x = 2y + 3x \]

From the phase plots of the two models, we see that neither structure is asymptotically stable, but the resulting phase plot obtained by combining the two structure shows that there are no unusual motion characteristics on the line \( x = 0 \) other than possible discontinuities on motion direction.

The line \( \sigma = 0 \) contains only endpoints of those trajectories coming from both sides of the line and these points constitute a special trajectory along the \( \sigma = 0 \) line, representing motion called a sliding mode.

Thus, a phase trajectory of this system generally consists of two parts, representing two modes of the system. The first part is the reaching mode, in which the trajectory starting from anywhere on the phase plane moves towards a switching line and reaches the line in finite time. The second part is the sliding mode in which the trajectory asymptotically tends to the origin of the phase plane.

### 3.2.1 Brief History of VSC

The history of VSC development is marked by three stages of development - the early stage of VSC, the stage of VSC for multi-input linear systems and the stage of complete VSC development.
Figure 3.3: Phase Portraits. (a) For System I  (b) For System II (c) Overall System
During the early stage, each VSC system was modelled by either a high-order, linear differential equation with a single input:

\[ x^{(n)} + a_n x^{(n-1)} + \cdots + a_2 x^{(1)} + a_1 x = bu \]  \hspace{1cm} (3.11)

or by its equivalent state space model in controllable canonical form

\[ \begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= x_3 \\
&\vdots \\
\dot{x}_n &= - \sum_{i=1}^{n} a_i x_i + bu
\end{align*} \hspace{1cm} (3.12) \\
\dot{x}_n &= - \sum_{i=1}^{n} a_i x_i + bu \hspace{1cm} (3.13) \]

The Switching surface was defined in a special quadratic form:

\[ S(x) = x_1(c_1 x_1 + c_2 x_2 + \cdots + c_n x_n) \]  \hspace{1cm} (3.14)

And the structure of the control was described by:

\[ u = \psi x_1 \]

where

\[ \psi = \alpha \quad \text{when} \quad S(x) > 0. \]

\[ = \beta \quad \text{when} \quad S(x) < 0. \]

\( \alpha \) and \( \beta \) are state dependent gains and are chosen to satisfy the reaching condition. Later on, the Variable Structure Systems theory was extended to multi-input, multi-
output (MIMO) systems.

The general system is of the form,

$$\dot{x} = Ax + Bu$$  \hspace{1cm} (3.15)

where $\dim x = n$ and $\dim u = m$, an $m$ dimensional linear vector switching function $S(x)$ was postulated for the VSC. The control structure for each of the $m$ inputs was described as:

$$u_i(x) = \psi^+(x) \quad \text{when} \quad S_i(x) > 0.$$  
$$= \psi^-(x) \quad \text{when} \quad S_i(x) < 0.$$  

where $i = 1, 2, \ldots, m$ and every scalar switching function $S_i(x)$ was linear in the state variables rather than quadratic.

This VSC theory was overshadowed by the popular linear control system design techniques and the important robustness properties of the VSC system were not yet fully recognized or appreciated.

The present stage represents the period where great attention given to VSC systems. The first is the existence of a general VSC design method for complex systems. The second is a full recognition of the property of perfect robustness of a VSC system with respect to system perturbations and disturbances.
3.2.2 Basic Notion of VSS Theory

Consider the $n^{th}$ order linear time-invariant (LTI) system in phase variable form:

\[
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= x_3 \\
&\vdots \\
\dot{x}_n &= -\sum_{i=1}^{n} a_i x_i + bu
\end{align*}
\] (3.16)

Consider the control given by:

\[
U(x) = \begin{cases} 
  u^+(x) & \text{if } S(x) > 0 \\
  u^-(x) & \text{if } S(x) < 0 
\end{cases}
\] (3.17)

where $u^+(x) \neq u^-(x)$ and each is chosen to satisfy the reaching condition defined by the pair of inequalities:

\[
\begin{align*}
&\dot{S}_i > 0. \quad \text{when} \quad S_i < 0. \\
&\dot{S}_i < 0. \quad \text{when} \quad S_i > 0 \quad i = 1, \ldots, m
\end{align*}
\]

or equivalently,

\[
S_i \dot{S}_i < 0 \quad i = 1, \ldots, m
\]

The Switching function $S(x)$ is defined by:

\[
S(x) = c_1 x_1 + c_2 x_2 + \cdots + c_n x_{n-1} + x_n
\] (3.18)
which defines a surface

\[ c_1 x_1 + c_2 x_2 + \cdots + c_n x_{n-1} + x_n = 0 \]

in the \( n \) dimensional phase space.

Since Eqn. (3.17) is in phase variable form, the coefficients in the switching surface, define the characteristic equation of the sliding mode.

During the sliding mode, \( S(x) \) remains zero and thus,

\[ x_n = -c_1 x_1 - c_2 x_2 - \cdots - c_{n-1} x_{n-1} \]

The differential equation of the system in sliding mode becomes:

\[
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= x_3 \\
\vdots \\
\dot{x}_{n-1} &= -c_1 x_1 - c_2 x_2 - \cdots - c_{n-1} x_{n-1}
\end{align*}
\]

(3.19)

Thus the \( n^{th} \) order system behaves like an \((n-1)^{th}\) order system during the sliding mode with the advantage that its dynamics are independent of system parameters.

When the states of the system cross the switching surface \( S(x) = 0 \), and enters the region \( S(x) < 0 \), the value of \( u(x) \) is altered from \( u^+(x) \) to \( u^-(x) \). The state of the system will immediately recross the switching surface and enter the region \( S(x) > 0 \) resulting in the value of \( u(x) \) being re-altered from \( u^-(x) \) to \( u^+(x) \). The system state is constrained to remain on the switching surface \( S(x) = 0 \) by the VSC controller.
which oscillates between the values $u^+(x)$ and $u^-(x)$. The condition under which the system state will move toward, reach and slide along the switching surface is called the reaching condition.

3.2.3 Design of VSC

The design of VSC systems consists of two independent stages. The first is the construction of the switching surface so that the original system or plant restricted to the surface responds in a desired manner. There are various design procedures for constructing these surfaces [26].

In the second stage, a VSC system is designed to drive the state of the system from any initial state in state space to reach the switching surface in finite time. This process is called the reaching mode.

Reaching Conditions and the Reaching mode

The condition under which the state will move towards and reach a sliding surface is called a reaching condition. The system trajectory under the reaching condition is called the reaching mode or reaching phase.

Different approaches can be used for specifying the reaching condition in the design of VSC systems. They may be designed by a direct switching function (DSF) approach, by a Lyapunov function approach, or by a reaching law approach.
The DSF design approach uses the following reaching condition:

\[
\lim_{S(x) \to 0^+} \dot{S}(x) < 0 \quad \text{and} \quad \lim_{S(x) \to 0^-} \dot{S}(x) > 0
\]

The Lyapunov function design approach uses the following reaching condition:

\[
V(x, t) = S^T(x)S(x) > 0 \quad \text{where} \quad \dot{V}(x, t) < 0
\]

The Reaching law approach uses the following law:

\[
\dot{S}(x) = -kS(x) - qsgn(S(x)) \quad (3.20)
\]

The reaching law approach not only establishes the reaching condition but also specifies the dynamic characteristics of the system during the reaching phase.

The Control Law

Design of the VSC control law depends on two factors:

- The choice of a sliding mode entering scheme.
- Whether or not the structure of the control law has been prespecified.

Whether the structure of the control is free or preassigned at the outset, the objective is to satisfy a reaching condition.

In the case of free structure of control, the reaching law approach (Eqn. (3.20)) can be used where \(k\) and \(q\) are positive gains. The term, \(-kS(x)\), forces the system state to approach the switching surface faster when \(|S(x)|\) is large. The term \(-qsgn(S(x))\), is used to counteract the system parameter variations and external
disturbances present in the system.

In some cases, it is convenient to preassign the structure of the VSC and then determine the values of the controller gains such that the desired reaching law is satisfied. There are two types of preassigned VSC structures. The Relay Control type has the following preassigned structure:

\[
    u(x) = \begin{cases} 
        K^+ & \text{if } S(x) > 0 \\
        K^- & \text{if } S(x) < 0 
    \end{cases} \tag{3.21}
\]

The values of \( K^+ \) and \( K^- \) are chosen to satisfy the desired reaching condition.

The linear feedback with switched gains type has the following preassigned structure:

\[
    u = \psi x
\]

where

\[
    \psi_{ij} = \alpha_{ij} \quad \text{where} \quad S_i(x)x_j > 0.
\]

\[
    \psi_{ij} = \beta_{ij} \quad \text{where} \quad S_i(x)x_j < 0.
\]

with \( i=1 \) to \( m \) and \( j=1 \) to \( n \) and \( \psi_{ij} \) is an \( m \times n \) matrix and the state dependent gains \( \alpha \) and \( \beta \) are chosen to satisfy the desired reaching condition.

### 3.2.4 Chattering

One of the underlying assumptions in the design and analysis of VSC systems is that the control can be switched from one value to another at infinite speed. But practically, it is impossible to achieve the high switching control that is necessary to most VSC designs. There are several reasons for this. One reason is the presence
of finite time delays for control computation. The second cause is the limitations of physical actuators.

Since it is impossible to switch the control at infinite rate, chattering always occurs in the sliding and steady-state modes of a VSC system. In the steady state, chattering appears as a high-frequency oscillation about the desired equilibrium point and may also serve as a source to excite the unmodeled high frequency dynamics of the system. Since chattering is almost always objectionable, significant research effort has been directed at eliminating or reducing its effects. Two of the main approaches proposed are the Continuation Approach and Tuning the Reaching Law approach.

The Continuation Approach

In many VSC designs, the control contains terms that are relay like in nature. The ideal relay characteristic is practically impossible to implement, so one approach to reduce the chatter is to replace relay control by a saturating continuous approximation. In state space, a boundary layer around the switching surface is introduced. Within this boundary layer, the control is chosen to be a continuous approximation of the switching function. An interpretation is that no high-gain control is used near the surface. A consequence of the continuation method is that invariance is lost. The system possesses robustness that is a function of the boundary layer width. The continuation approach eliminates the high-frequency chattering at the price of losing invariance. A high degree of robustness can still be maintained with a small boundary layer width, but significant delays in the control actuator may dictate the need for a "thicker" boundary layer. In the extreme case, large amplitude
low-frequency oscillation may result and the system may cease to possess any variable structure behavior. The invariance and robustness properties of the system no longer exist.

**Tuning the Reaching Law Approach**

Chattering can be reduced by tuning parameters $q_i$ and $k_i$ in the reaching law

$$\dot{S}_i = -q_i sgn(S_i) - k_i S_i \quad i = 1, \ldots, m.$$ 

Near the switching surface, $s_i \approx 0$, so $|\dot{S}_i| \approx q_i$. By choosing the gain $q_i$ small, the momentum of the motion will be reduced as the system trajectory approaches the switching surface. As a result, the amplitude of the chatter will be reduced. However, $q_i$ cannot be chosen equal to zero because the reaching time would become infinite; the system fails to be a sliding mode control system. A large value for $k_i$ increases the reaching rate when the state is not near the switching surface. In summary, chattering is a hindrance to the widespread use of VSC in many practical control systems. Elimination or reduction of chattering remains an important and challenging problem.

**3.2.5 Robustness of VSC**

Robustness is one of the most distinguishing properties of VSC systems. For a plant represented by either a linear or nonlinear high-order differential equation, the differential equation of the sliding mode can be entirely independent of effects due to modeling error and external disturbances. Thus the sliding mode is said to be
invariant to modeling error and disturbances. The invariance property requires that certain matching conditions be satisfied.

Consider a general linear system of the form

$$\dot{x} = (A + \Delta A)x + Bu + f(t)$$  \hspace{1cm} (3.22)

where $\Delta A$ and $f(t)$ represent the modeling error and external disturbance, respectively. If there exist $\Delta \tilde{A}$ and $\tilde{f}(t)$ such that matching conditions

$$\Delta A = B \Delta \tilde{A} \quad \text{and} \quad f(t) = B \Delta \tilde{f}$$

are satisfied, then the sliding mode is invariant. The physical meaning of matching conditions is that all modeling uncertainties and disturbances should enter the system through the control channel.

The same result can be extended to nonlinear systems

$$\dot{x} = A(x) + \Delta A(x) + B(x)u + f(x, t)$$  \hspace{1cm} (3.23)

For the more general case, where $B(x)$ is also perturbed

$$\dot{x} = A(x) + \Delta A(x) + B(x)u + \Delta B(x)u + f(t)$$

where $\Delta A(x)$, $\Delta B(x)$ and $f(t)$ represent the uncertainty and external disturbance, respectively. If there exist $\Delta \tilde{A}$, $\Delta \tilde{B}$ and $\tilde{f}(t)$ such that matching conditions,

$$\Delta A(x) = B(x)\Delta \tilde{A}(x)$$
\[ \Delta B(x) = B(x) \Delta \tilde{B}(x) \]

\[ f(t) = B(x) \Delta \tilde{f}(t) \]

are satisfied for certain \( \Delta \tilde{A}, \Delta \tilde{B} \) and \( \tilde{f} \), then the sliding mode is invariant.

3.2.6 Attractive Features of VSS

1. VSS is capable of producing robust systems that are sometimes invariant to plant parameter variations and disturbances. The invariance property requires that specific conditions of matching be satisfied. The physical meaning of matching conditions is that all system parameter variations and external disturbances should enter the system through the control channel only.

2. Another attractive feature of VSS is decoupling the VSC design problem into two independent stages. During the first stage, a sliding mode is created and in the second stage, the desired motion on the sliding mode is provided by an appropriate equation designed by the closed-loop eigenvalue placement technique.

3. The system in sliding mode can be described by a dynamic system of lower order than the original system.

4. High speed of response without loss of stability. This is obtained by increasing the gains of the VSC system and by a suitable choice of switching surfaces.

5. Straight forward synthesis of asymptotically stable systems by combining two or more structures which may be unstable on their own.
Chapter 4

Plant Augmentation

Methodology

The switching of the control at infinite rate when designing a controller using VSS theory may excite unmodelled high frequency plant dynamics and may jeopardize the system performance. In this chapter, a filtering method is proposed to remove the excessive chatter in the control signal.

Three points are stressed at the outset for Nonlinear Systems [23, 26, 51]:

1. Basic concepts and the fundamental theory of VSC are similar to those for linear systems.

2. The derivation of a control $u(x)$ is similarly simple and straightforward.

3. But the analysis of sliding mode and the search for the corresponding switching function becomes a more difficult problem.

For nonlinear systems, various state transformations are used to put the differential equations of the system in one of several possible canonical forms.
Consider the nonlinear system

$$\dot{x} = f(x, p) + g(x, p)u$$  (4.1)

where $f(x, p)$ and $g(x, p)$ are smooth vector fields on $\mathbb{R}^n$ and $p$ is a set of uncertain parameters [9]. The expressions for $f$ and $g$ are known but the values of the parameters $p$ are unknown. Let us assume that the system is feedback equivalent, under a (local) diffeomorphic coordinate transformation ($T$) and a nonlinear state feedback input coordinate transformation ($S$),

$$z = T(x, p) \simeq T$$  (4.2)

$$u = S(x, p, v) = \alpha(x, p) + \beta(x, p)v \simeq \alpha + \beta v$$  (4.3)

to a linear controllable canonical form as described in Chapter 3.

The system is augmented by a pure integrator, which serves as a buffer, so that the chattering appears at the augmented system rather than the original system. By transforming the augmented system model into a controllable canonical form, the coefficients of the switching surface will define the characteristic equation of the sliding mode [58]. The VSC technique is then applied to the augmented plant which consists of the original plant and the pure integrator. This procedure for designing a VSC ensures the stability of the augmented system and reduces the control chattering to a great extent.

After the feedback linearization, now we have a linearized system. The uncertainties and external disturbances can be represented by $\Delta p$ which can be estimated using
the Luenberger observer. Now, by properly designing the switching surface and estimating the $\Delta p$, we can design the controller for the augmented linearized system. Note that $z_{n+1} = v$ where $v$ is the linearizing control and $z$ is the linearizing state vector. And now, by ensuring that the reaching condition is satisfied and adjusting the magnitude ($q$) of the signum term such that it neutralizes the effects of system uncertainties and external disturbances, we can obtain the linearizing control signal. And then the original control signal for the nonlinear system, which is a function of the linearizing state vector and the linearizing control, can be obtained.

Firstly, the design of VSC for the unaugmented plant is considered. The linearized system is a LTI which can be augmented with an integrator and a VSC can be developed for the augmented system. The development of the VSC for a SISO (LTI) in canonical form is presented next.

Consider a single-input single-output (LTI) plant [40] with a single input disturbance $f(t)$ represented by the controllable canonical form:

$$
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \ldots & 0 \\
0 & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
-a_1 & -a_2 & \cdots & -a_n \\
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
\end{bmatrix}
+ 
\begin{bmatrix}
0 \\
0 \\
\vdots \\
b \\
\end{bmatrix}
\begin{bmatrix}
u \\
f(t) \\
\vdots \\
d \\
\end{bmatrix}
\quad (4.4)
$$

$$
y = 
\begin{bmatrix}
1 & 0 & \ldots & 0 \\
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
\end{bmatrix}
$$
The VSC is defined by:

\[
    u(x) = \begin{cases} 
    u^+(x) & \text{if } S(x) > 0 \\
    u^-(x) & \text{if } S(x) < 0 
    \end{cases} \tag{4.5}
\]

where the switching function \( S(x) \) is

\[
    S(x) = c_1 x_1 + c_2 x_2 + \cdots + x_n \tag{4.6}
\]

and defines a surface:

\[
    c_1 x_1 + c_2 x_2 + \cdots + x_n = 0 \tag{4.7}
\]

From the reaching law condition:

\[
    \dot{S}(x) = -kS(x) - q \text{sgn}(S(x)) \tag{4.8}
\]

where \( k \) and \( q \) are positive gains.

Taking the derivative of Eqn. (4.6), we get

\[
    \dot{S}(x) = c_1 \dot{x}_1 + c_2 \dot{x}_2 + \cdots + \dot{x}_n \tag{4.9}
\]

From Eqn. (4), Eqn. (4.8) and Eqn. (4.9), the controller is given by

\[
    u = -\frac{1}{b} \left[ kS(x) + \sum_{i=1}^{n} (c_i - a_i)x_i + q \text{sgn}(S(x)) + df(t) \right] \tag{4.10}
\]
All quantities are known except \( f(t) \). So, replace \( df(t) \) by a known quantity \( f_c \), which yields,

\[
u = -\frac{1}{b}[kS(x) + \sum_{i=1}^{n}(c_{i-1} - a_i)x_i + qsgn(S(x)) + f_c]
\]

(4.11)

where, \( f_c \) should be chosen to satisfy the reaching condition.

Substituting Eqn. (4) and Eqn. (4.11) into Eqn. (4.9) and simplifying, we get:

\[
\dot{S}(x) = -KS(x) - qsgn(S(x)) - (f_c - df(t))
\]

(4.12)

Comparing Eqn. (4.12) to Eqn. (4.8), shows that an additional term, \((f_c - df(t))\) appears in the reaching dynamics due to the arrangement for handling the unknown disturbance \( f(t) \).

Assume some priori bounds on \( df(t) \), i.e. \( f_l(t) \leq df(t) \leq f_u(t) \) where \( f_l(t) \) and \( f_u(t) \) are the lower and upper boundary limits of \( df(t) \). To ensure the reaching condition, \( f_c \) should dominate the unknown \( df(t) \). Therefore,

When \( S(x) > 0 \), set \( f_c = f_u(t) \) to guarantee that \( \dot{S}(x) < 0 \)

When \( S(x) < 0 \), set \( f_c = f_l(t) \) to guarantee that \( \dot{S}(x) > 0 \)

Define

\[
f_{c_1} = \frac{(f_u(t) + f_l(t))}{2} \quad \text{and} \quad f_{c_2} = \frac{(f_u(t) - f_l(t))}{2}
\]

then

\[
f_c = (f_{c_1} + f_{c_2}s\text{gn}(S(x)))
\]

(4.13)
The final control law is given by:

\[
u = -\frac{1}{b}[kS(x) + qsng(S(x)) + \sum_{i=1}^{n}(c_{i-1} - a_{i})x_{i} + (f_{c1} + f_{c2}sgn(S(x)))]\]  \hspace{1cm} (4.14)

The above VSC design is capable of making the system robust against external disturbances as long as the range of \(df(t)\) is known. The conventional approach in designing a VSC system is to set \(f_c\) as given in Eqn. (4.13). A large magnitude for \(f_c\) results in a robust system over a wide range of disturbances but with a large chattering amplitude.

### 4.1 Augmenting the plant with an integrator

When the plant is augmented with an integrator \((1/s)\), as shown in Figure 4.1., the chattering appears at the input of the augmented plant rather than the original plant. The state equations after plant augmentation become:

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
-a_1 & -a_2 & \cdots & -a_n & b \\
0 & 0 & \cdots & 0 & 0
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} +
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} \cdot u_a +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
1
\end{bmatrix} f(t) \hspace{1cm} (4.15)
\]
Figure 4.1: The augmented plant concept
\[ y = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} \]  

(4.16)

The switching function now becomes:

\[ S(x) = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n + x_{n+1} \]  

(4.17)

which defines a surface

\[ c_1 x_1 + c_2 x_2 + \cdots + c_n x_n + x_{n+1} = 0 \]  

(4.18)

in the \( n + 1 \) dimensional phase space.

The state equations of Eqn. (4.15) can be transformed into the controllable canon-

![Diagram](image)

Figure 4.2: Model of the augmented plant with a pure integrator
The coefficients in the switching function in Eqn. (4.18) define the characteristic equation of the sliding mode and the motion along the sliding surface can be considered as the dynamics of a system with \( n \) eigenvalues.

Let \( \lambda_1, \lambda_2, \ldots, \lambda_n \) be the desired \( n \) eigenvalues with negative real parts. Define

\[
S(x) = (D - \lambda_1)(D - \lambda_2) \cdots (D - \lambda_n)x_1 \quad (4.20)
\]

where \( D = (d/dt) \), then the coefficients of the switching surface can be obtained as:

\[
c_1 = (-1)^n(\lambda_1 \lambda_2 \cdots \lambda_n)
\]
\[
c_2 = (-1)^{n-1}(\lambda_2 \lambda_3 \cdots \lambda_n + \lambda_1 \lambda_3 \cdots \lambda_n + \lambda_1 \lambda_2 \cdots \lambda_{n-1})
\]
\[
c_n = -(\lambda_1 + \lambda_2 + \cdots + \lambda_n) \quad (4.21)
\]

Differentiating Eqn. (4.17), substituting Eqn. (4.19) and equating it to Eqn. (4.8), we get,

\[
u_a = -\frac{1}{b}[kS(x) + \sum_{i=1}^{n+1}(c_{i-1} - a_i)x_i + q\text{sgn}(S(x)) + (c_n - a_n)df(t)] \quad (4.22)\]
The magnitude of the signum term \( q \) is determined by taking the time derivative of Eqn. (4.17) and substituting the untransformed augmented plant model, Eqn. (4.15), with Eqn. (4.22) into it. This gives

\[
\dot{S}(x) = G_1(x) - \frac{1}{b} K S(x) - \frac{a}{b} \text{sgn}(S(x)) + c_n (b x_{n+1} + df(t)) - \frac{(c_n - a_n)}{b} df(t)
\]  
(4.23)

where

\[
G_1(x) = \left[ \sum_{i=1}^{n-1} (C_i x_{i+1}) - \sum_{i=1}^{n} (c_n a_i) x_i - \sum_{i=1}^{n+1} \frac{(c_{i-1} - a_{i-1})}{b} x_i \right]
\]  
(4.24)

Note that \( x_{n+1} = u \). By appropriate substitution,

\[
\dot{S}(x) = G_2(x) - \frac{1}{b} K S(x) + \left[ c_n - \frac{(c_n - a_n)}{b^2} \right] (bu + df(t)) - \frac{a}{b} \text{sgn}(S(x)) + \frac{F}{b}
\]

where

\[
G_2(x) = \left[ \sum_{i=1}^{n-1} (C_i x_{i+1}) - \sum_{i=1}^{n} (c_n a_i + \frac{(c_{i-1} - a_{i-1})}{b} x_i) \right]
\]  
(4.25)

and

\[
F = \frac{(c_n - a_n)(1-b)}{b} df(t)
\]  
(4.26)
To ensure the reaching condition is satisfied, \( q \) is chosen so as to dominate the unknown \( F \). This will be achieved if

- When \( S(x) > 0 \), set \( q > |F| \) to guarantee that \( \dot{S}(x) < 0 \)
- When \( S(x) < 0 \), set \( q < |F| \) to guarantee that \( \dot{S}(x) > 0 \)

If \( q \) is set accordingly, then we can have a robust system over a wide range of disturbance with suppressed chattering.

### 4.2 Adaptive VSC Methodology

Augmenting the system by a pure integrator will reduce the control chattering. The effect of control chattering can further be reduced by adjusting the magnitude of the signum term of Eqn. (4.8) according to the estimated system uncertainties and external disturbances present in the system. An \( n + 1 \) order Luenberger observer is required to estimate these uncertainties and disturbances through the observer reconstruction error equations. Thus, for a nominal case, the magnitude of the signum term is zero and control chattering does not exist. However, when system uncertainties and disturbances are present the magnitude of the signum term is adjusted to be large enough to maintain the robustness of the augmented system.

The state equations of a general single-input single-output (LTI) augmented plant.
with system uncertainties and a single input disturbance, are represented by

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} = \begin{bmatrix}
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
-\bar{a}_1 & -\bar{a}_2 & \cdots & -\bar{a}_n & b \\
0 & 0 & \cdots & 0 & 0
\end{bmatrix} \begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} + \begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
1
\end{bmatrix} u_a + \begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
0
\end{bmatrix} f(t) \tag{4.27}
\]

where the system parameter uncertainties are expressed by:

\[
\bar{a}_i = (a_i + \Delta a_i) \quad \text{for } i = 1, 2, \ldots, n.
\]

with \(a_i\), the nominal value and \(\Delta a_i\) is the uncertainty in \(\bar{a}_i\).

The switching function, \(S(x)\), is defined by

\[
S(x) = c_1x_1 + c_2x_2 + \cdots + c_nx_n + x_{n+1} \tag{4.28}
\]

which defines a surface

\[
c_1x_1 + c_2x_2 + \cdots + c_nx_n + x_{n+1} = 0 \tag{4.29}
\]

in the \(n + 1\) dimensional phase plane. The coefficients of the switching surface, Eqn. (4.29), define the characteristic equation of the sliding mode, if Eqn. (4.27) is
described in controllable canonical form. Eqn. (4.27) may be written as

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
-a_1 & -a_2 & \cdots & -a_n & b \\
0 & 0 & \cdots & 0 & 0
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
1
\end{bmatrix} u_a +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
0
\end{bmatrix} \Delta p
\]

(4.30)

where

\[
\Delta p = -\sum_{i=1}^{n} \Delta a_i x_i + df(t)
\]

(4.31)

The controllable canonical form of Eqn. (4.27) is

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & \cdots & \vdots \\
0 & 0 & \cdots & 0 \\
0 & -a_1 & \cdots & -a_n
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
b
\end{bmatrix} u_a +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
-a_n
\end{bmatrix} \Delta p
\]

(4.32)
The corresponding Luenberger Observer State equations are represented by:

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
-a_1 & -a_2 & \cdots & -a_n & b \\
0 & 0 & \cdots & 0 & 0
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix}
+ 
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
1
\end{bmatrix}
\begin{bmatrix}
u_a \\
e_1
\end{bmatrix}
\] (4.33)

The Luenberger Observer is basically an image of the plant model with additional input [32] [31]. This additional input is proportional to the error in observed output as is defined by \(e_1\). The Luenberger Observer has its inputs and the outputs of the system whose state is approximated and has a state vector that is linearly related to the desired approximation [57]. Since the Luenberger observer is dependant on

![Figure 4.3: Block diagram of the Luenberger Observer](image)

the plant model, system parametric uncertainties and external disturbances can be estimated by the observer reconstruction error defined as \(e_i = x_i - \hat{x}_i; \ i = 1, 2, \cdots n\). So, subtracting Eqn. (4.27) from Eqn. (4.33), we get the observer-error
state equations as

\[
\begin{bmatrix}
\dot{e}_1 \\
\dot{e}_2 \\
\vdots \\
\dot{e}_n \\
\dot{e}_{n+1}
\end{bmatrix} = \begin{bmatrix}
-g_1 & 1 & \cdots & 0 & 0 \\
-g_2 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
-(a_1 + g_n) & -a_2 & \cdots & -a_n & b \\
-g_{n+1} & 0 & \cdots & 0 & 0
\end{bmatrix} \begin{bmatrix}
e_1 \\
e_2 \\
\vdots \\
e_n \\
e_{n+1}
\end{bmatrix} + \begin{bmatrix}
e_1 \\
e_2 \\
\vdots \\
e_n \\
e_{n+1}
\end{bmatrix} \Delta p \tag{4.34}
\]

Thus,

\[
\dot{e}_n = -g_ne_1 - \sum_{i=1}^{n} a_ie_i + b\dot{e}_{n+1} + \Delta p \tag{4.35}
\]

or

\[
\Delta p = g_ne_1 + \sum_{i=1}^{n} a_ie_i + \dot{e}_n - b\dot{e}_{n+1} \tag{4.36}
\]

Figure 4.4 shows how system uncertainties and external disturbances are estimated by augmenting the original system by a pure integrator and by a Luenberger observer.

### 4.2.1 Design of Adaptive VSC

The VSC technique is applied to the augmented plant which consists of the original plant and the pure integrator as shown in Figure 4.1. The VSC is determined directly from the reaching law method,

\[
\dot{S}(x) = -kS(x) - q\text{sgn}(S(x)) \tag{4.37}
\]
where $k$ and $q$ are positive gains.

To design the VSC system, one proceeds by taking the time derivative of Eqn. (4.6), which gives,

$$
\dot{S}(x) = c_1 \dot{x}_1 + c_2 \dot{x}_2 + \cdots + c_n \dot{x}_n + \dot{x}_{n+1}
$$

Equating Eqn. (4.8) and Eqn. (4.38), substituting Eqn. (4.32) into it, and then solving for the control $u_a$ yields

$$
u_a = -\frac{1}{b}[kS(x) + \sum_{i=1}^{n+1}(c_{i-1} - a_{i-1})x_i + qsgn(S(x)) + (c_n - a_n)\Delta p]
$$
To make sure that the reaching condition is always satisfied, substitute Eqn. (4.32) and Eqn. (4.39) into Eqn. (4.9), to get

\[
\dot{S}(x) = G_2(x) - \frac{1}{b} [kS(x) - (c_n - (c_n - a_n)b)(bu + \Delta p) + q\text{sgn}(S(x)) - F\Delta p]
\]

where

\[
G_2(x) = \sum_{i=1}^{n-1} (C_i x_{i+1}) - \sum_{i=1}^{n} (c_n a_i + \frac{(c_{i-1} - a_{i-1})}{b} x_i)
\]  
(4.40)

\[
F = \frac{(c_n - a_n)(1 - b)}{b}
\]  
(4.41)

Note that \(x_{n+1} = u\).

The reaching condition is always satisfied as long as the magnitude of the signum term \(q\) dominates the uncertainty. The magnitude of the signum term is chosen as:

\[
q = z \cdot |F\Delta p|
\]  
(4.42)

where \(z\) is a positive constant which is used to make \(q\) just large enough to handle and neutralize the effects of system uncertainties and external disturbances.

In this way, the reaching condition is satisfied and we can adjust the magnitude of the signum term such that it neutralizes the effects of system uncertainties and external disturbances. And we can obtain the linearizing control signal for the nonlinear system. The original control signal for the nonlinear system (\(U_{org}\)), which is a function of the linearizing state vector and the linearizing control can be obtained.
The above scheme is summarized as shown in Figure 4.5. But the linearizing control

Figure 4.5: Proposed Scheme (States of the NL system are Accessible.)

requires completely accessible states. This does not happen very often in practice. A state observer can be designed to implement the linearizing control law with the observer estimates. But even though the observer may be a 'good' and fast one, some instabilities may appear. When the states of the nonlinear system are not accessible, we have to introduce a nonlinear observer to reconstruct the states of the
nonlinear system and proceed in the same way as in the case of accessible states. To this end, we use the idea of Solsona et al. [36] for designing the nonlinear observer. This approach guarantees the stability of the whole system i.e. the plant plus observer if state feedback control is used. This scheme is summarized as shown in Figure 4.6

Figure 4.6: Proposed Scheme (States of the NL system are not Accessible.)
4.2.2 Inaccessible States case

When the states of the nonlinear system are not accessible, then the linearizing feedback law can be implemented by designing a nonlinear observer and using the state estimates for feedback.

Now consider the SISO nonlinear system [36],

\[
\dot{x} = f(x) + g(x)u \tag{4.43}
\]

\[
y = h(x) \tag{4.44}
\]

When we linearize this system, the linearizing state feedback law, \( u = \alpha(x) + \beta(x)v \) requires completely accessible states. This does not happen very often. We may design a state observer and implement the feedback law with the observer estimates. But this may lead to instability of the whole system i.e. the plant plus observer. So, we have to set proper sufficient condition that makes possible the stabilization of the whole system: i.e. the plant plus observer.

The above nonlinear system can be linearized through coordinate transformation and nonlinear feedback law.

So, the system is given by

\[
\dot{z} = Az + bv + \Delta p \tag{4.45}
\]

\[
y = cz \tag{4.46}
\]
where $\Delta p$ is the uncertainty in the parameters of the nonlinear system and

$$A = \begin{bmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 1 \\
0 & 0 & 0 & \cdots & 0
\end{bmatrix}, \quad b = \begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
b_1
\end{bmatrix} \quad (4.47)$$

The observer is of the form

$$\dot{\hat{z}} = A\hat{z} + bv + \Delta p + L(y - \hat{y}) \quad (4.48)$$

$$\hat{y} = c\hat{z} \quad (4.49)$$

with $G = [g_1 \cdots g_n]^T$, the vector of observer gains. The error ($e = z - \hat{z}$) dynamics are given by

$$\dot{e} = (A - Lc)e$$

An observerable pair $(c, A)$ implies that $L$ may be designed so that $(A - Lc)$ is a stability matrix. Now for both systems to be in comparable coordinates, $\hat{z}$ must be transformed into $\hat{w} = \phi(\hat{z})$ and feed $u = \alpha(\phi(\hat{z})) + \beta(\phi(\hat{z}))v$ back to the input of the plant, to complete the 'linearization'. The observer must also undergo the previous
feedback. Hence the whole feedback system, plant plus observer is given by

\[
\begin{bmatrix}
0 & 1 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots & \vdots & \cdots & \vdots \\
0 & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
l_1 & 0 & \cdots & 0 & -l_i & 1 & 0 & \cdots & 0 \\
l_2 & 0 & \cdots & 0 & -l_2 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots & \vdots & \cdots & \vdots \\
l_{n-1} & 0 & \cdots & 0 & -l_{n-1} & 0 & 0 & \cdots & 1 \\
l_n & 0 & \cdots & 0 & -l_n & 0 & 0 & \cdots & 0
\end{bmatrix}
\begin{bmatrix}
W \\
W + \cdots v + \cdots \Delta p \quad (4.50)
\end{bmatrix}
\]

with \( W = [w_1 \ w_2 \ \cdots \ w_n \ \tilde{w}_1 \ \tilde{w}_2 \ \cdots \ \tilde{w}_n]^T \).

If we feedback the whole system with \( v = -k\tilde{w} \), the matrix of the linear part becomes.

\[
J = \begin{bmatrix}
A & -bk \\
Lc & A - Lc - bk
\end{bmatrix}
\quad (4.51)
\]

where \( k = [k_1 \ \cdots \ k_n] \)

Because the pair \((A, b)\) is controllable and the pair \((c, A)\) is observable, there exist constant matrices \( k \) and \( L \) such that the eigenvalues of \( J \) are, a bit far from the \( j\omega \) axis, in the left half-plane, i.e. \( J \) is a stability matrix.

Thus the whole system, nonlinear plant plus the observer, remains stable. This is true for the \( v = -k\tilde{w} \) case [36] but not necessarily for the VSC controller.
4.2.3 Replacing the integrator with Low Pass Filter

The insertion of a 1st-order low-pass filter ahead of the plant was originally suggested by Zinober et al. [3]. The low-pass filter is not considered as a part of the system during the design process of the VSC.

The design procedure of Adaptive VSC can also be extended to include systems augmented with 1st-order low-pass filters. Here we consider the low-pass filter as a part of the system as shown in Figure 4.7 and design the controller. The augmented plant is given by

$$
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n \\
\dot{x}_{n+1}
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
-a_1 & -a_2 & \cdots & -a_n & b \\
0 & 0 & \cdots & 0 & -\frac{1}{\tau}
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} +
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n \\
x_{n+1}
\end{bmatrix} +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
\frac{1}{\tau}
\end{bmatrix} u_a +
\begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
0
\end{bmatrix} \Delta p \ (4.52)
$$

where $\tau$ is the time constant. And $\Delta p$ is the uncertainty in the system. Now, following the same procedure as in the case of integrator, an adaptive VSC can be designed.
Chapter 5

Simulation Results

The performance of the proposed scheme will be investigated and an extensive simulation study will be performed in this chapter.

5.1 Example 1

Consider a Nonlinear System as shown below:

\[
\begin{align*}
\dot{x}_1 &= x_2 + \sin(x_1) \\
\dot{x}_2 &= a_1 U_{\text{org}} + a_2 x_1^2
\end{align*}
\]  \hspace{1cm} (5.1)

Let \( a_1 = 2 \) and \( a_2 = 10 \) and let the parameters \( a_1 \) and \( a_2 \) be perturbed by \( \Delta a_1 \) and \( \Delta a_2 \), respectively.

Consider the new set of state variables,

\[
z_1 = x_1
\]
\[ z_2 = x_2 + \sin x_1 \] (5.2)

then, the new state equations are

\[
\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= a_2 z_1^2 + z_2 \cos x_1 + a_1 U_{org} + \Delta p
\end{align*}
\] (5.3)

where \( \Delta p \) is the Uncertainty. The nonlinearities can be cancelled by the control law of the form

\[ U_{org} = -\frac{1}{a_1} (bv - a_2 z_1^2 - z_2 \cos x_1) \] (5.4)

where \( v \) is an equivalent input to be designed i.e. the linearizing control from the original control signal for the nonlinear system may be obtained, leading to a linear input-state relation

\[
\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= bv + \Delta p
\end{align*}
\] (5.5)

After Linearization, the linearized system in state space representation is given by:

\[
\begin{bmatrix}
\dot{z}_1 \\
\dot{z}_2
\end{bmatrix} = \begin{bmatrix}
0 & 1 \\
0 & 0
\end{bmatrix} \begin{bmatrix}
z_1 \\
z_2
\end{bmatrix} + \begin{bmatrix}
0 \\
b
\end{bmatrix} v + \begin{bmatrix}
0 \\
1
\end{bmatrix} \Delta p
\] (5.6)
where

\[
\Delta p = \Delta a_2 x_1^2 + \Delta a_1 U_{org} + f(t)
\]  

(5.7)

Here \( f(t) = 5\sin(2\pi t) \) is the external disturbance.

When the system is augmented by an integrator, the canonical controllable form of the augmented linearized system is given by:

\[
\begin{bmatrix}
    z_1 \\
    \dot{z}_2 \\
    \dot{z}_3
\end{bmatrix}
= \begin{bmatrix}
    0 & 1 & 0 \\
    0 & 0 & 1 \\
    0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
    z_1 \\
    z_2 \\
    z_3
\end{bmatrix}
\]

\[
+ \begin{bmatrix}
    0 \\
    0 \\
    b
\end{bmatrix}
\begin{bmatrix}
    v_a + 1 \\
    \Delta p
\end{bmatrix}
\]

(5.8)

Note that \( z_3 = v \). The switching function of the augmented system is

\[
S(z) = 902.25z_1 + 60z_2 + z_3
\]  

(5.9)

where the coefficients of the \( S(x) \) are chosen according to

\[
c_1 = -(\lambda_1\lambda_2)
\]

\[
c_2 = -(\lambda_1 + \lambda_2)
\]

(5.10)

where \( \lambda_1 \) and \( \lambda_2 \) represent the desired closed-loop eigenvalues which are chosen as
The desired eigenvalues are
\[ \lambda_{1,2} = -30 \pm j1.5 \] \hfill (5.11)

The augmented control law is given by:
\[ v_a = -\left(\frac{1}{30}\right)[10S(z) + 902.5z_2 + 60z_3 + q\text{sgn}(S(z))] \] \hfill (5.12)

Here \( b = 30 \) and \( k = 10 \). And \( q \) is given by:
\[ q = z \left| \frac{(c^2 - a^2)(1 - b)}{b} \right| \Delta p \] \hfill (5.13)

where \( z = 30 \)

Since the unknown system uncertainty \((\Delta a_2 z_1^2 + \Delta a_1 U_{org})\) and the external disturbance \(f(t)\) are included in \(\Delta p\), the magnitude of the signum term, \(q\), in the VSC system is adjusted according to \(\Delta p\). As seen from Equation 5.13, \(q\) will be large enough to maintain the robustness of the system against system uncertainties and external disturbance. When these unknown uncertainties and disturbance are absent, the magnitude of the signum term is zero and chattering does not exist.

The Luenberger Observer matrix, \(G\) is synthesized by ITAE Butterworth standard forms for closed-loop responses for optimal performance indices. The eigenvalues of the \(A - GH\) matrix are determined by the characteristic polynomial
\[ |sI - (A - GH)| = s^3 + 2\omega_0 s^2 + 2\omega_0^2 s + \omega_0^3 \] \hfill (5.14)
where $\omega_0 = 2$. The elements of the matrix $G$ are

\[ g_1 = 2\omega_0 \quad \text{and} \quad g_2 = 2\omega_0^2 \]  
\[ g_3 = \omega_0^3/b \]  
\[ G = [4 \quad 8 \quad 8/30] \]

For inaccessible states of the Nonlinear System case, an Observer is designed for the nonlinear System as mentioned earlier and the same two cases are repeated. The Observer for this Nonlinear system is given by:

\[
\begin{align*}
\dot{x}_1 &= \dot{x}_2 + \sin(x_1) + l_1(x_1 - \hat{x}_1) \\
\dot{x}_2 &= a_1U_{org} + a_2x_1^2 + l_2(x_1 - \hat{x}_1)
\end{align*}
\]

The output of the Nonlinear system is $y = x_1$ with $G_1 = [l_1 \quad l_2]^T$, the vector of observer gains. Following the procedure of designing the observer for a Nonlinear system as mentioned in Chapter 4, the observer gains vector, $G$ can be taken as $L = [10 \quad 10]^T$ so that the necessary and sufficient conditions for the stability of the nonlinear system plus its observer are satisfied with the feedback controller.

Simulations of the closed-loop augmented system were performed using matlab.

### 5.1.1 Results

- **Case 1**: When the two parameters $a_1$ and $a_2$ have sinusoidal parameter uncertainty with 50% variations i.e. $\Delta a_1 = \sin(2\pi t)$ and $\Delta a_2 = 5\sin(2\pi t)$. Ref Figure 5.5.
• **Case 2:** When the two parameters $a_1$ and $a_2$ have sinusoidal Parameter Uncertainty with 50% variations and an external disturbance $f(t) = 5\sin(2\pi t)$ is considered. Ref Figure 5.6.

• Figure 5.1 and Figure 5.2 show the simulation results when the plant is not augmented with an integrator. From these simulation results we can see that there is a large of chattering appearing in the linearizing control(v) as well as the control input signal to the original nonlinear plant. And in addition to that, we can see the chatter appearing in the states also.

• Figure 5.3 shows the simulation results for Example 1. when the states of the system are accessible and only the constant parameter uncertainties are considered. And Figure 5.4 shows the simulation results when both constant parameter uncertainties and external disturbance are considered.

• Figure 5.5 shows the simulation results for Example 1. when the states of the system are accessible and only the sinusoidal parameter uncertainties are taken into consideration.

• Figure 5.5 (a) shows the estimation of the system parameter uncertainties, $\Delta p = (\Delta a_2 x_1^2 + \Delta a_1 U_{org})$, which is done by Eqn. 4.36.

• Figure 5.5 (b) shows the input to the augmented linearized system and Figure 5.5 (d) shows the control, which is the input to the original system. Here we can see the magnitude of chatter at the input of the augmented linearized system but the presence of chatter in the control signal of the original nonlinear system is very much suppressed.
Figure 5.1: Example 1. Accessible States: Const. Par. Uncertainty (Without Integrator)
Figure 5.2: Example 1. Accessible States: Sine par. Uncertainty. (Without Integrator)
Figure 5.3: Example 1. Accessible States: Only Constant Par. Uncertainty
Figure 5.4: Example 1. Accessible States: Constant Par. Uncrt. with ext. disturbance
Figure 5.5: Example 1. Accessible States: Case 1.
Figure 5.6: Example 1. Accessible States: Case 2.
Figure 5.7: Example 1. Accessible States: Case 1. (with integrator replaced by LPF)
Figure 5.8: Example 1. Accessible States: Case 2. (with integrator replaced by LPF)
- Figure 5.5 (c) shows the adaptive value of the magnitude of the signum term \( q \), determined by Eqn. 5.13. Initially, the value of \( q \) is very large as the value of the estimate of the parameter uncertainty is large. The magnitude of the signum term should be large enough to maintain the robustness of the system.

- Augmenting the linearized system by a pure integrator will also suppress state variable chattering. The chatter is not visible in the output as shown in Figure 5.5 (f). So, the given system is stable and robust against system parameter uncertainties.

- Figure 5.6 shows the simulation results for Ex.1 when the states of the system are accessible and both the system parameter uncertainties and external disturbance are taken into consideration.

- As in the previous case, the given system is stable and robust against parameter uncertainties and external disturbances. \( \Delta p = \Delta a_2 x_1^2 + \Delta a_1 U_{org} + f(t) \) where \( f(t) = 20 \sin(2\pi 0.4t) \). These uncertainties are estimated by \( \Delta p \) given by Eqn. 4.36 as shown in the Figure 5.6 (a).

- Figure 5.6 (c) shows the adaptive value of the magnitude of the signum term \( q \).

- Figure 5.6 (f) shows the control signal for the original nonlinear system. We can see from Figure 5.6 (b) and (f), the chattering of the input signal to the original system is reduced.

- Figure 5.7 and Figure 5.8 show the simulation results for Example 1. when the states of the system are accessible and the integrator is replaced by a 1st-order low-pass filter. Both the cases are considered here also.
Figure 5.9: Example 1. Inaccessible States: Case 1.
Figure 5.10: Example 1. Inaccessible States: Case 2.

Table 5.1: Results of Example 1.

- Figure 5.9 and Figure 5.10 show the simulation results when the states of the nonlinear system are inaccessible. Here we have designed the observer for the nonlinear system [36] which guarantees the stability of the whole system, the plant plus the observer. The same two cases are repeated.

- We can see from Figure 5.9 and Figure 5.10 that the magnitude of chattering of the input signal to the augmented linearized system and the original system is more when compared to the case of accessible states. And the states also take a longer settling time.

From Table 5.1, we can get the summary of the simulation of Example 1. We can see that the inaccessible states case requires more control effort and longer settling times of the states when compared to the accessible states case. And the controller is robust enough to deal with both the parameter uncertainties and external disturbances. The chattering index can be measured by the number of switchings in the control signal. We can see that the number of switchings in the control signal for the augmented linearized system is much more than that of the control signal for the nonlinear system.
5.2 Example 2

Consider a single link joint flexible manipulator represented by:

\[
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= -\frac{Mgl}{I} \sin(x_1) - \frac{k}{I} (x_1 - x_3) \\
\dot{x}_3 &= x_4 \\
\dot{x}_4 &= \frac{k}{J} (x_1 - x_3) + \frac{1}{J} U_{org}
\end{align*}
\] (5.18)

Let \( p_1 = \frac{Mgl}{I} = 10, k = 5, I = 1 \) and \( J = 0.5 \).

Now let the parameters \( p_1 \) and \( k \) be perturbed by \( \Delta p_1 \) and \( \Delta k \), respectively.

Consider the new set of state variables,

\[
\begin{align*}
z_1 &= x_1 \\
z_2 &= x_2 \\
z_3 &= -p_1 \sin x_1 - \frac{k}{I} (x_1 - x_3) \\
z_4 &= -p_1 x_2 \cos x_1 - \frac{k}{I} (x_2 - x_4)
\end{align*}
\] (5.19)

then, the new state equations are

\[
\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= z_3 - [\Delta p_1 \sin x_1 + \frac{\Delta k}{I} (x_1 - x_3)] \\
\dot{z}_3 &= z_4 \\
\dot{z}_4 &= l_1 + l_2 + l_3 + \Delta p_1 [p_1 \cos x_1 + \frac{k}{I}] 
\end{align*}
\] (5.20)
where

\[
\begin{align*}
l_1 &= p_1 x_2^2 \sin x_1 + p_1^2 \sin x_1 \cos x_1 \\
l_2 &= \frac{p_1 k}{I} (x_1 - x_3) \cos x_1 + \frac{k^2}{II} (x_1 - x_3) \\
l_3 &= \frac{p_1 k}{I} \sin x_1 + \frac{k^2}{I^2} (x_1 - x_3)
\end{align*}
\]  

(5.21)

and

\[
\Delta p = \Delta p_1 \sin x_1 + \frac{\Delta k}{I} (x_1 - x_3)
\]

(5.22)

The nonlinearities can be cancelled by the control law of the form

\[
\mathcal{L}_{\text{org}} = -\frac{JI}{k} [l_1 + l_2 + l_3 - bv]
\]

(5.23)

where \(v\) is an equivalent input to be designed lead to a linear input-state relation.

After linearization, the linearized system is given by:

\[
\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= z_3 - \Delta p \\
\dot{z}_3 &= z_4 \\
\dot{z}_4 &= v + \Delta p (p_1 \cos x_1 + \frac{k}{I})
\end{align*}
\]

(5.24)

where \(\Delta p = \Delta p_1 \sin x_1 - \frac{\Delta k}{k} (p_1 z_1 + z_3)\).

Performing another coordinate transformation and assuming constant uncertainty.
the final linearized system is given by

\[
\begin{bmatrix}
\dot{w}_1 \\
\dot{w}_2 \\
\dot{w}_3 \\
\dot{w}_4
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
w_1 \\
w_2 \\
w_3 \\
w_4
\end{bmatrix}
+ \begin{bmatrix}
0 \\
0 \\
0 \\
b
\end{bmatrix} v + \begin{bmatrix}
0 \\
0 \\
0 \\
1
\end{bmatrix} \Delta p_{new}
\]  

(5.25)

where

\[
\Delta p_{new} = \Delta p\left(p_1 \cos w_1 + \frac{k}{I}\right) - (w_3 \cos w_1 - w_2^2 \sin w_1)
\]

\[
(\Delta p_1 - \frac{\Delta k p_1}{k})
\]

\[
+ \frac{\Delta k \Delta p}{k} (p_1 \cos w_1 + \frac{k}{I}) + \frac{\Delta k}{k} v + f(t)
\]

(5.26)

Here \(f(t) = 20 \sin(2\pi 0.4t)\) is the external disturbance

and

\[
v = l_1 + l_2 + l_3 + \frac{k}{J I} U_{org}
\]

(5.27)
When the system is augmented by an integrator, the canonical controllable form of the augmented linearized system is given by:

\[
\begin{bmatrix}
\dot{w}_1 \\
\dot{w}_2 \\
\dot{w}_3 \\
\dot{w}_4 \\
\dot{w}_5
\end{bmatrix}
= \begin{bmatrix}
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
w_1 \\
w_2 \\
w_3 \\
w_4 \\
w_5
\end{bmatrix}
\]

\[
+ \begin{bmatrix}
0 \\
0 \\
0 \\
0 \\
b
\end{bmatrix} v_a
+ \begin{bmatrix}
0 \\
0 \\
0 \\
0 \\
0
\end{bmatrix} \Delta p_{new}
\]

(5.28)

Note that \( w_5 = v \). The switching function of the augmented system is

\[
S(w) = 1500w_1 + 1150w_2 + 235w_3 + 32w_4 + w_5
\]

(5.29)

where the coefficients of the \( S(x) \) are chosen according to the formula as mentioned before. The desired eigenvalues are

\[
\lambda_{1,2,3,4} = -15, -10, -5, -2
\]

(5.30)

The augmented control law is given by:

\[
v_a = -(\frac{1}{30})[10S(w) + 1500w_2 + 1150w_3 + 235w_4 + 32w_3 + qsgn(S(w))] 
\]

(5.31)
Here $b = 30$, $k = 10$ and $q$ is given by:

$$q = z \left( \frac{(c5 - a5)(1 - b)}{b} \right) | \Delta p_{new}$$

(5.32)

where $z = 30$ and $a5 = 0$.

The Luenberger Observer matrix $G$ is synthesized by ITAE Butterworth standard forms for closed-loop responses to get optimal performance indices. The eigenvalues of the $A - GH$ matrix are determined by the characteristic polynomial

$$| sI - (A - GH) | = s^3 + 3.23 \omega_0 s^4 + 5.23 \omega_0^2 s^3 + 5.23 \omega_0^3 s^2 + 3.23 \omega_0^4 s + \omega_0^5 / b$$

(5.34)

where $\omega_0 = 5$. The elements of the matrix $G$ are

$$g_1 = 3.23 \omega_0, \quad g_2 = 5.23 \omega_0^2, \quad g_3 = 5.23 \omega_0^3, \quad g_4 = 3.23 \omega_0^4$$

$$g_5 = \omega_0^5 / b$$

(5.35)

$$G = \begin{bmatrix} 16.15 & 130.75 & 653.75 & 2018.8 & 104.16 \end{bmatrix}$$

When the states of the NL system are inaccessible, then an observer can be designed as mentioned in Chapter 4. The Observer for this Nonlinear system is given by:

$$\dot{x}_1 = \dot{x}_2 + l_1(x_1 - \dot{x}_1)$$
$$\dot{x}_2 = -\frac{MgI}{l} \sin(x_1) - \frac{k}{l}(x_1 - \dot{x}_2) + l_2(x_1 - \dot{x}_1)$$
$$\dot{x}_3 = \dot{x}_4 + l_3(x_1 - \dot{x}_1)$$
\[ \dot{x}_4 = \frac{k}{f}(x_4 - \dot{x}_3) + \frac{1}{f}U_{\text{org}} + l_4(x_1 - \dot{x}_1) \]  \hspace{1cm} (5.36)

The output of the Nonlinear system is \( y = x_1 \) with \( bfL = [l_1 \hspace{0.2cm} l_2 \hspace{0.2cm} l_3 \hspace{0.2cm} l_4]^T \), the vector of observer gains. Following the procedure of designing the observer for a Nonlinear system as mentioned in Chapter 4, the observer gains vector, \( L \) can be taken as \( L = [13 \hspace{0.2cm} 61 \hspace{0.2cm} 107 \hspace{0.2cm} 53]^T \) so that the necessary and sufficient conditions for the stability of the nonlinear system plus its observer are satisfied with the feedback controller.

Simulations of the closed-loop augmented system were performed using Matlab.

\subsection{5.2.1 Results}

- **Case 1**: When the two parameters \( p_1 \) and \( k \) have constant Parameter Uncertainty with 25\% variations. Ref Figure 5.11.

- **Case 2**: When the two parameters \( a_1 \) and \( a_2 \) have constant Parameter Uncertainty with 25\% variations and an external disturbance \( f(t) = \sin(0.8\pi t) \) is considered. Ref Figure 5.12.

- Figure 5.11 shows the simulation results for Example 2, when the states of the system are accessible and only the parameter uncertainties are taken into account.

- From Figure 5.11 (a) and (c), we can see the presence of chatter at the input of the augmented linearized system, \( v_a \), but the presence of chatter in the control signal of the original nonlinear system, \( U_{\text{org}} \), is suppressed.
• Figure 5.11 (b) shows the adaptive value of the magnitude of the signum term \( q \), determined by Eqn. 5.13.

• Figure 5.11 shows the simulation results for Example 2, when the states of the nonlinear system are accessible and both the parameter uncertainties and external disturbances are taken into account.

• As seen from the simulation results, the given system is stable and robust against the parameter uncertainties and external disturbance, \( f(t) \) given by \( f(t) = \sin(0.8\pi t) \).

• Figure 5.11 (b) shows the adaptive value of the magnitude of the signum term \( q \).

• As evident from Figure 5.11 (a) and (c), despite the external disturbance, the presence of chatter in the control signal of the original nonlinear system is suppressed.

• Figure 5.13 and Figure 5.14 are the simulation results for the inaccessible states case. We can see from Figure 5.9 and Figure 5.10 that the magnitude of chattering of the input signal to the augmented linearized system and the original system is more when compared to the case of accessible states. And the states also take a longer settling time.
Figure 5.11: Example 2. Accessible States: Case 1.
Figure 5.12: Example 2. Accessible States: Case 2.
Figure 5.13: Example 2. Inaccessible States: Case 1.
Figure 5.14: Example 2. Inaccessible States: Case 2.

Table 5.2: Results of Example 2.

From Table 5.2, we can get the summary of the simulation of Example 2. We can see that the inaccessible states case requires more control effort and longer settling times of the states when compared to the accessible states case. And similar is the case when external disturbance is also considered.
5.3 Example 3

Consider the Nonlinear System:

\[
\begin{align*}
\dot{x}_1 &= x_2 + x_2^2 + ax_3^2 + U_{org} \\
\dot{x}_2 &= x_3 + \sin(x_1 - x_3) \\
\dot{x}_3 &= ax_3^2 + U_{org}
\end{align*}
\] (5.37)

Let \( a = 10 \) and be perturbed by \( \Delta a \).

Consider the new set of state variables.

\[
\begin{align*}
z_1 &= x_1 - x_3 \\
z_2 &= x_2 + x_2^2 \\
z_3 &= (1 + 2x_2)[x_3 + \sin(x_1 - x_3)]
\end{align*}
\]

then, the new state equations are

\[
\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= z_3 - [\Delta p_1 \sin x_1 + \frac{\Delta k}{l}(x_1 - x_3)] \\
\dot{z}_3 &= l_1 + l_2 + l_3 + l_4 U_{org} + \Delta p
\end{align*}
\] (5.38)

where

\[
\begin{align*}
l_1 &= ax_3^2 + 2ax_2x_3^2 + 2x_3^2 + 2x_3\sin(x_1 - x_3) \\
l_2 &= (x_2 + x_2^2)(1 + 2x_2)\cos(x_1 - x_3)
\end{align*}
\]
\[ l_3 = 2[x_3 \sin(x_1 - x_3) + \sin^2(x_1 - x_3)] \]
\[ l_4 = 1 + 2x_2 \quad (5.39) \]

and

\[ \Delta p = \Delta a(x_3^2 + 2x_2x_3^2) \quad (5.40) \]

The nonlinearities can be cancelled by the control law of the form

\[ \mathcal{U}_{ord} = -\frac{1}{l_4}[l_1 + l_2 + l_3 - b \nu] \quad (5.41) \]

where \( \nu \) is an equivalent input to be designed lead to a linear input-state relation

\[ \begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= z_3 \\
\dot{z}_3 &= bv + \Delta p
\end{align*} \quad (5.42) \]

After Linearization, the linearized system in state space representation is given by:

\[ \begin{bmatrix}
\dot{z}_1 \\
\dot{z}_2 \\
\dot{z}_3
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
z_1 \\
z_2 \\
z_3
\end{bmatrix}
+ \begin{bmatrix}
0 \\
0 \\
b
\end{bmatrix} \nu + \begin{bmatrix}
0 \\
0 \\
1
\end{bmatrix} \Delta p \quad (5.43) \]
where

\[ \Delta p = \Delta a(x_3^2 + 2x_2x_3^2) + f(t) \]  \hspace{1cm} (5.44)

Here \( f(t) = 2\sin(2\pi t) \) is the external disturbance.

When the system is augmented by an integrator, the canonical controllable form of the augmented linearized system is given by:

\[
\begin{bmatrix}
\dot{z}_1 \\
\dot{z}_2 \\
\dot{z}_3 \\
\dot{z}_4 \\
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
z_1 \\
z_2 \\
z_3 \\
z_4 \\
\end{bmatrix}
+ 
\begin{bmatrix}
0 \\
0 \\
0 \\
b \\
\end{bmatrix}
\begin{bmatrix}
\nu_a + \Delta p \\
0 \\
0 \\
1 \\
0 \\
\end{bmatrix}
\]

\hspace{1cm} (5.45)

Note that \( z_3 = \nu \). The switching function of the augmented system is

\[ S(z) = 290z_1 + 129z_2 + 20z_3 + z_4 \]  \hspace{1cm} (5.46)

where the coefficients of the \( S(x) \) are chosen according to the formulae as mentioned earlier.

The desired eigenvalues are

\[ \lambda_{1,2} = -5 \pm j2, \quad \lambda_3 = -10 \]
and

The augmented control law is given by:

\[ v_a = -\left( \frac{1}{30} \right) [10S(z) + 290z_2 + 129z_3 + 20z_4 + q sgn(S(z))] \quad (5.47) \]

Here \( b = 30 \) and \( k = 10 \). And \( q \) is given by:

\[ q = \frac{(c3 - a3)(1 - b)}{b} \text{ } | \Delta p \] \quad (5.48)

where \( z = 30 \)

Since the unknown system uncertainty \( \Delta a(x_3^2 + 2x_2x_3^2) \) and external disturbance \( f(t) \) are estimated by \( \Delta p \), the magnitude of the signum term, \( q \), in the VSC system is adjusted according to \( \Delta p \). As seen from Equation 5.48, \( q \) will be large enough to maintain the robustness of the system against system uncertainties and external disturbance. When these unknown uncertainties and disturbance are absent, the magnitude of the signum term is zero and chattering does not exist.

The Luenberger Observer matrix, \( \mathbf{G} \) is synthesized by ITAE Butterworth standard forms for closed-loop responses. The eigenvalues of the \( \mathbf{A} - \mathbf{GH} \) matrix are determined by the characteristic polynomial

\[ | sI - (A - GH) | = s^4 + 2.6\omega_0 s^3 + 3.4\omega_0^2 s^2 + 2.6\omega_0^3 s + \omega_0^4 \] \quad (5.49)

where \( \omega_0 = 5 \). The elements of the matrix \( \mathbf{G} \) are

\[ g_1 = 2.6\omega_0, \quad g_2 = 3.4\omega_0^2, \quad g_3 = 2.6\omega_0^3 \text{ and } g_4 = \omega_0^4/b \]
\[ G = [13 \quad 85 \quad 195 \quad 20.8] \]

When the states of the NL system are inaccessible, then an observer can be designed as mentioned in Chapter 4. The Observer for this Nonlinear system is given by:

\[
\begin{align*}
\dot{x}_1 &= \dot{x}_2 + \dot{x}_2^2 + ax_3^2 + U_{\text{org}} + l_1(x_1 - \dot{x}_1) \\
\dot{x}_2 &= \dot{x}_3 + \sin(x_1 - \dot{x}_3) + l_2(x_1 - \dot{x}_1) \\
\dot{x}_3 &= ax_3^2 + U_{\text{org}} + l_3(x_1 - \dot{x}_1)
\end{align*}
\] (5.50)

The output of the Nonlinear system is \( y = x_1 \) with \( L = [l_1 \quad l_2 \quad l_3]^T \), the vector of observer gains. Following the procedure of designing the observer for a Nonlinear system as mentioned in Chapter 4, the observer gains vector, \( L \) can be taken as \( L = [20 \quad 20 \quad 10]^T \) so that the necessary and sufficient conditions for the stability of the nonlinear system plus its observer are satisfied with a feedback controller. Simulations of the closed-loop augmented system were performed using matlab.

### 5.3.1 Results

- **Case 1:** When the parameter \( a \) has sinusoidal Parameter Uncertainty with 50% variation. Ref Figure 5.15.

- **Case 2:** When the parameter \( a \) has sinusoidal Parameter Uncertainty with 50% variation and an external disturbance \( f(t) = \sin(\pi t) \) is considered. Ref Figure 5.16.
Figure 5.15: Example 3. Accessible States: Case 1.
Figure 5.16: Example 3. Accessible States: Case 2.
• Figure 5.15 shows the simulation results for Example 3. when the states of the system are accessible, and only the parameter uncertainties are taken into account.

• Figure 5.15 (a) shows the estimation of the system parameter variations given by $\Delta p$.

• From Figure 5.16 (b) and (c), we can see the presence of chatter at the input of the augmented linearized system, $v_a$, but the presence of chatter in the control signal of the original nonlinear system, $U_{org}$, is suppressed.

• Figure 5.11 (c) shows the output of the system. Here we can see that there is no presence of chatter in the output.

• Figure 5.16 shows the simulation results for Example 2. when the states of the nonlinear system are accessible and both the parameter uncertainties and external disturbances are taken into account.

• As seen from the simulation results, the given system is stable and robust against the parameter uncertainties and external disturbance. $f(t)$ given by $f(t) = \sin(\pi t)$.

• Figure 5.11 (a) shows the estimation of the system parameter variations.

• As evident from Figure 5.11 (b) and (c), inspite of the external disturbance, the presence of chatter in the control signal of the original nonlinear system is suppressed.
Figure 5.17: Example 3. Inaccessible States: Case 1.

Table 5.3: Results of Example 3.

- Figure 5.17 and Figure 5.18 are the simulation results for the inaccessible states case. We can see from Figure 5.17 and Figure 5.18 that the magnitude of chattering of the input signal to the augmented linearized system and the original system is more when compared to the case of accessible states. And the states also take a longer settling time.

From Table 5.3, we can get the summary of the simulation of Example 3. We can see that the inaccessible states case requires more control effort and longer settling times of the states when compared to the accessible states case. And similar is the case when external disturbance is also considered.
5.4 Comparison with Kanellakopoulos et al. Scheme

5.4.1 Kanellakopoulos et al. Method (Scheme 1)

Consider the example [23]

\[
\begin{align*}
\dot{x}_1 &= x_2 + \theta x_1^2 \\
\dot{x}_2 &= x_3 \\
\dot{x}_3 &= u 
\end{align*}
\] (5.51)

where \( \theta \) is an unknown constant parameter. This is a "benchmark" example of adaptive nonlinear regulation as it violates the restrictions and assumptions taken into consideration in the uncertainty-constrained schemes and the nonlinearity-constrained schemes proposed in [10,24 and 50]. Restrictions on the type of nonlinearities and assuming some geometric conditions in order to satisfy the matching conditions were set. But this example violates all the geometric conditions and growth assumptions mentioned in [10,24 and 50].

The adaptive control scheme involves successive estimation of the unknown constant parameter with the design of a new parameter estimator at each step. This method is a self-tuning parameter estimation type of adaptive scheme. The whole scheme results in solving the following set of differential equations of the adaptive system

\[
\begin{align*}
\dot{z}_1 &= -2z_1 + z_2 + z_1^2(\theta - \nu_1) \\
\dot{z}_2 &= -2z_2 + z_3 + 2z_1^2(1 + \nu_1 z_1)(\theta - \nu_2) \\
\dot{z}_3 &= -2z_3 + [4z_1^2(1 + \nu_1 z_1)(1 + \nu_2 z_1) + 2\nu_1 (x_2 + \nu_2 x_1^2)x_1^2 + 5z_1^5](\theta - \bar{\nu}_2) 
\end{align*}
\]
and

\[ \dot{\nu}_1 = z_1^3 \]
\[ \dot{\nu}_2 = 2z_2z_1^2(1 + \nu_1z_1) \]
\[ \dot{\nu}_3 = z_3[4z_1^2(1 + \nu_1z_1)(1 + \nu_2z_1) + 2nu_1(x_2 + \nu_2x_1^2)x_1^2 + 5z_1^6] \quad (5.53) \]

where \( \nu_1, \nu_2 \) and \( \nu_3 \) are the successive estimates of the parameter \( \theta \). And \( z \) is the linearized system.

### 5.4.2 Adaptive VSC Method (Scheme 2)

Considering the same example taken by Kanellakopoulos et al., we apply the adaptive VSC concept.

\[ \dot{x}_1 = x_2 + \theta x_1^2 \]
\[ \dot{x}_2 = x_3 \]
\[ \dot{x}_3 = u \quad (5.54) \]

Now let the parameters \( \theta \) be perturbed by \( \Delta \theta \).

After performing the Feedback Linearization with three coordinate transformations, the final linearized system is given by

\[
\begin{bmatrix}
\dot{w}_1 \\
\dot{w}_2 \\
\dot{w}_3
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
w_1 \\
w_2 \\
w_3
\end{bmatrix}
\]
\[
\begin{bmatrix}
0 \\
0 \\
b
\end{bmatrix} \cdot v + \begin{bmatrix}
0 \\
0 \\
1
\end{bmatrix} \Delta p
\] (5.55)

where

\[
\Delta p = 2\Delta \theta [x_1 x_3 + 2\theta x_1^2 x_2 + 2\theta^2 x_1^4 + 2\Delta \theta x_1^2 x_2 + 4\Delta \theta x_1^4 \\
+ \Delta \theta x_1^3 + x_2 + \theta x_1^2 + \Delta \theta x_1^2] + f(t)
\] (5.56)

Here \( f(t) = 20\sin(2\pi 0.4t) \) is the external disturbance.

When the system is augmented by an integrator, the canonical controllable form of the augmented linearized system is given by:

\[
\begin{bmatrix}
\dot{w}_1 \\
\dot{w}_2 \\
\dot{w}_3 \\
\dot{w}_4
\end{bmatrix} =
\begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
w_1 \\
w_2 \\
w_3 \\
w_4
\end{bmatrix} +
\begin{bmatrix}
0 \\
0 \\
b
\end{bmatrix} \cdot v_a + \begin{bmatrix}
0 \\
0 \\
1
\end{bmatrix} \Delta p
\] (5.57)

Note that \( w_4 = v \). The switching function of the augmented system is

\[
S(z) = 290w_1 + 129w_2 + 20w_3 + w_4
\] (5.58)
where the desired eigenvalues are

\[ \lambda_{1,2} = -5 \pm j2, \quad \lambda_3 = -10 \]

and

The augmented control law is given by:

\[ v_a = -\left(\frac{1}{30}\right)[10S(z) + 290z_2 + 129z_3 + 20z_4 + \text{sgn}(S(z))] \tag{5.59} \]

Here \( b = 20 \) and \( k = 5 \). And \( q \) is given by:

\[ q = z \left| \frac{(c3 - a3)(1 - b)}{b} \right| \Delta p \tag{5.60} \]

where \( z = \bar{z} \)

The Luenberger Observer matrix, \( G \) is synthesized by ITAE Butterworth standard forms for closed-loop responses. The eigenvalues of the \( A - GH \) matrix are determined by the characteristic polynomial

\[ | sI - (A - GH) | = s^4 + 2.6\omega_0 s^3 + 3.4\omega_0^2 s^2 + 2.6\omega_0^3 s + \omega_0^4 \tag{5.61} \]

where \( \omega_0 = 20 \). The elements of the matrix \( G \) are

\[ g_1 = 2.6\omega_0, \quad g_2 = 3.4\omega_0^2, \quad g_3 = 2.6\omega_0^3 \text{ and } g_4 = \omega_0^4/b \]

\[ G = \begin{bmatrix} 52 & 1360 & 20800 & 8000 \end{bmatrix} \]

Table 5.4: Comparison table for both schemes

### 5.4.3 Comparison

Simulations of this system were performed with $\theta = 2$ using the employing the two schemes and the results are compared. Three different cases are considered. They are as follows:

- **Case 1**: When the parameter $\theta$ has no uncertainty.

- **Case 2**: When the parameter $\theta$ has constant parameter uncertainty with 50% variation.

- **Case 3**: When the parameter $\theta$ has constant parameter uncertainty with 100% variation and an external disturbance $f(t) = 20sin(2\pi 0.4t)$ is considered.

From the simulation results and comparison table of both the schemes, we can conclude the following:

- Scheme 2 requires much less control effort when compared to Scheme 1.

- The states of the system using scheme 2 take a smaller settling time when compared to scheme 1.
• Scheme 2 works very well in the presence of external disturbances also where as Scheme 1 does not stabilize the states of the system inspite of much larger control effort when compared to Scheme 2.

• The parameter estimation through Scheme 2 is much better than that to Scheme 1.

Chapter 6

Conclusions & Recommendations

6.1 Conclusions

In this research work, we have concentrated on reducing the chattering phenomenon in the variable structure controller using the plant augmentation scheme and the adaptive VSC methodology and proposed a scheme by which a VSC controller could be designed for uncertain nonlinear systems which do not satisfy the matching conditions. To summarize, the following contributions have been made:

- Combining the concepts of Feedback Linearization and Variable Structure Control, a robust controller for uncertain nonlinear systems has been designed.

- New methodology to reduce the chatter in the Variable Structure Controller.

- Uncertainty Estimation is performed online.

- Case of inaccessible states of the uncertain nonlinear system is also considered which takes into consideration the stability of the whole system i.e. the plant plus the nonlinear observer.
• Good Comparison of results has been made with the present techniques dealing with the control of Nonlinear Systems.

6.2 Recommendations

Some recommendations for future work:

• Extension to MIMO case can also be considered.

• Throughout this work we considered regulation problems only. This scheme may also be extended to tracking problems also.

• Theoretical study can also be undertaken to analyze the proposed method in order to gain insight about local and global stability properties.
Appendix A

The transformation of the state equations of the augmented system into the controllable canonical form

The state equation

\[ \dot{x} = Ax + Bu_a + Df(t) \]

\[ y = Hx \] (1)

is transformable to a controllable canonical form. [29]

\[ \dot{x}_c = A_c x_c + B_c u_a + D_c f(t) \]

\[ y_c = H_c x_c \] (2)

if the matrix

\[ S = [B \quad AB \quad A^2B \quad \cdots \quad A^nB] \] (3)
is nonsingular. If that is true, then there exits a singular transformation

\[ x_c = Qx \]

The transformation matrix \( Q \) is given by

\[
Q = \begin{bmatrix}
Q_1 \\
Q_1 A \\
\vdots \\
Q_1 A^n
\end{bmatrix}
\]  

where

\[ Q_1 = \begin{bmatrix} 1 & 0 & \cdots & 0 \end{bmatrix} \begin{bmatrix} S^{-1} \end{bmatrix} \]

and

\[ A_c = T \cdot A \cdot T^{-1}, \quad B_c = T B, \quad H_c = H T^{-1}, \quad \text{and} \quad D_c = T D \]

where \( T = bQ \).
