**Dedicated to my beloved brothers and sisters**

**Dedicated to my friends and those who love me more than anything**

## ACKNOWLEDGMENTS

I express my gratitude and praise to ALMIGHTY ALLAH, the creator of universe, who is beneficent and merciful, guided us in difficult and congeal circumstance, who endowed us with the will to complete this project. Great respect our Holy Prophet Hazrat Muhammad (PBUH), who taught us to learn till lap of grave.

I am highly thankful to Department of chemical Engineering, King Fahad University of Petroleum and Minerals (KFUPM), Saudi Arabia for awarding me scholarship to pursue my PhD. Special thanks to King Abdul-Aziz City for Science and Technology (KACST) through the Science & Technology Unit at King Fahd University of Petroleum & Minerals (KFUPM) for funding this work through project # 11-ENE1635-04 as part of the National Science, Technology and Innovation Plan (NSTIP).

I express my sincere thanks to my advisor Prof. Ibnelwaleed Ali Hussein for supervising my research. Without his technical and moral support I would not have been able to complete my work. My hearties thanks to my committee members: Dr.Shakeel Ahmed, Dr. Khalil Harrabi, Dr. **Reyad A. Shawabkeh and Dr. Mohammed Ba-Shammakh for their useful comments and suggestion. I am thankful to** Dr. Amir Al Ahmed and Mr. Mogtaba B. Mekki for helping me in the experimentation. I would also like to thank to Dr. Saleem (former advisor) and Dr. Nouar tabet for their helpful suggestions. Special thanks to Dr.Ghulam Mustafa Mamoor from University of Engineering and Technology (UET), Lahore, Pakistan for guiding me in my research. I would also like to acknowledge the Center of Research Excellence for Renewable Energy at KFUPM for providing me the laboratory facility.

Last but not least, thanks to my parents, brothers, sisters and friends in my country prayed day and night for my success

## ABSTRACT

Full Name : [UMER MEHMOOD]  
Thesis Title : [DEVELOPMENT OF NEW DYE SENSITIZED MATERIALS FOR SOLAR CELL APPLICATIONS]  
Major Field : [CHEMICAL ENGINEERING]  
Date of Degree : May, 2015]

Solar cells based on organic materials are among the promising candidates for the implementation of the next generation of solar cells. For their advantage, to be flexible compared to the counterpart based on silicon. Its synthesis might be achieved with low cost; however its efficiency remains a challenging issue to be deeply studied and improved. It becomes the focus of optimizing many parameters as: the adequate use of the polymer, the efficient way of collecting the generated electron-hole; which is the aim of this proposal.

Dye-sensitized solar cells (DSCs) constitute a novel class of hybrid organic solar cells. Organic donor- $\pi$ -acceptor dyes are an interesting alternative to the standard metal-organic complexes used in DSCs. This provides the solar cell flexibility and may make them inexpensive. The aim is to design and synthesize novel Donor-  $\pi$ -Acceptor molecules in order to increase the efficiency of organic solar cells. Efficient photovoltaic conversion and stable performance could be demonstrated with few classes of donor systems, such as diphenylamine, diuorenylaminophenyl, coumarin etc. It has been concluded that Cyano Acrylic acid is one of the best acceptor group. Therefore, to synthesize a novel series of Donor Acceptor Based Organic molecules to screen their efficiency in solar applications we couple few different donor and  $\pi$ -conjugated bridges to cyano acrylic acid in a different fashion. After the synthesis of the organic molecules, solar cells will be fabricated, tested and compared with the existing commercial solar cells. After the synthesis of the organic molecules by our collaborators in India, systematic studies and characterization of the molecules are going to be carried out by our team at KFUPM Laboratories. Results will be published and presented in international conferences..

**Keywords:** Dye-sensitized solar cells; solar cell performance, organic solar cells|

## ملخص الرسالة

الاسم الكامل: عمر محمود

عنوان الرسالة: تطوير مواد صباغة توعية جديدة لتطبيقات الخلايا الشمسية

التخصص: هندسة كيميائية

تاريخ الدرجة العلمية: : مايو 2015

. من مزاياها أنها مرنة مقارنة مع نظيراتها المبنية من السيلكون. كما يمكن تصنيعها بتكلفه اقل، ولكن تبقى كفاءتها وطرق تحسينها مسألة تحتاج لمزيد البحث و الدراسة. أصبح تحسين الكفاءة يعتمد على عدة محاور منها: الاستخدام الملائم للمواد العضوية (البلوليمر) ، وإيجاد وسائل فعالة لجمع الشحنات المولدة، الذي هو الهدف من هذا المشروع. الخلايا الشمسية الصبغية (DSSCs) تشكل فئة جديدة من الخلايا الشمسية العضوية المختلطة. المواد العضوية المانحة- $\pi$ - المتقبلة الأصباغ تعتبر من البدائل المهمة للمركبات المعدنية-العضوية المستخدمة في الخلايا الشمسية الصبغية (DSSCs) . وهذا يوفر مرونة الخلايا الشمسية، ويجعل إنتاجها غير مكلف. الهدف من هذا المشروع هو تصميم وتركيب جزيئات مانحة- $\pi$ - متقبلة جديدة من أجل زيادة كفاءة الخلايا الشمسية العضوية.

كفاءة التحويل الكهروضوئية العالية والأداء المستقرة يمكن الحصول عليها مع فئات قليلة من النظم المانحة مثل (diphenylamine) ، (diuorenylaminophenyl) ، (coumarin) الخ... وقد خلصت الدراسة إلى أن حمض الاكريليك (Cyano Acrylic Acid) هو واحد من أفضل المجموعة المتقبلة. لذلك ، لتركيبة سلسلة جديدة من الجزيئات العضوية المانحة- المتقبلة لمعرفة كفاءتها في تطبيقات الطاقة الشمسية، سنعمل على مزوجة أعداد مختلفة من المانحة و  $\pi$  - الجسور المترافق لحمض الاكريليك (Cyano Acrylic Acid) بطرق مختلفة.

بعد تركيب الجزيئات العضوية ، سيتم تصنيع الخلايا الشمسية واختبار كفاءتها ومقارنتها مع الخلايا الشمسية التجارية القائمة. بعد تركيب الجزيئات العضوية من قبل المتعاونين لدينا في الهند ، الدراسة المنهجية لهذه الجزيئات العضوية و معرفة خصائصها سوف تنفذ من قبل فريقنا في مختبرات جامعة الملك فهد. وسيتم نشر النتائج وتقديمها في المؤتمرات الدولية.

كلمات البحث: صيغ الخلايا الشمسية؛ أداء خلايا الطاقة الشمسية، خلايا الطاقة الشمسية العضوي

# CHAPTER 1

## INTRODUCTION

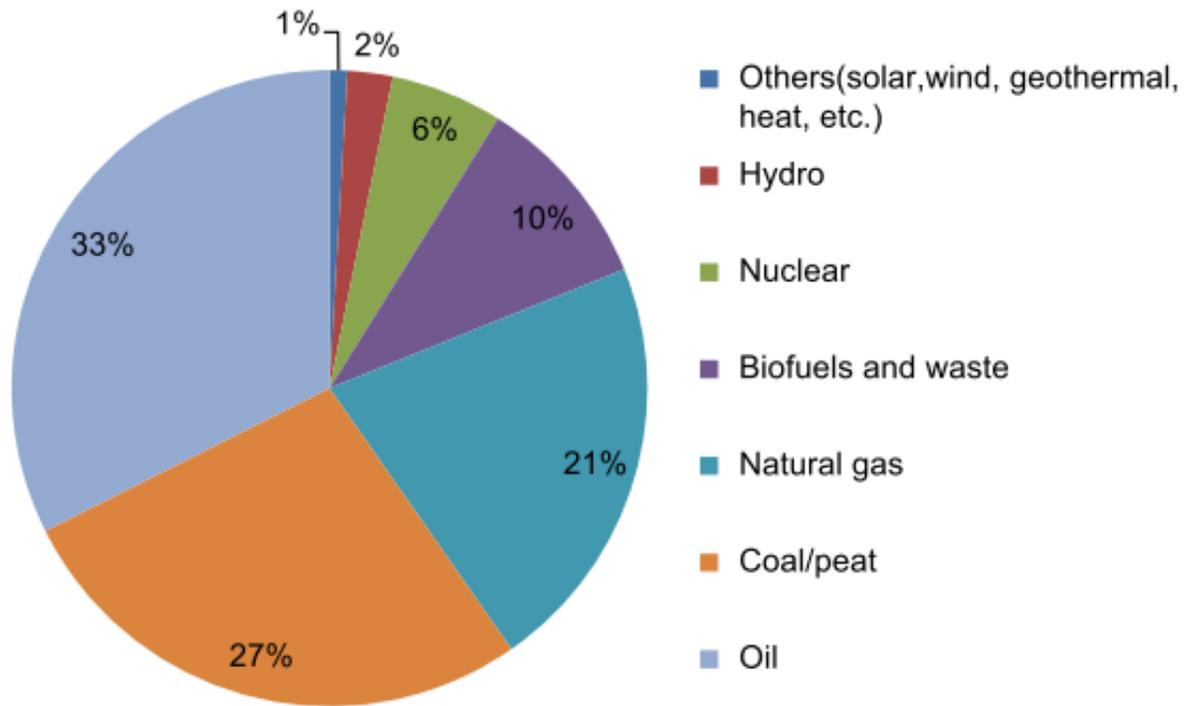

### 1.1. Energy

Energy is the driving force for development, economic growth, automation, and modernization. Energy usage and demand are increasing globally and researchers have taken this seriously to fulfill future energy demands [1,2]. At present global energy sources are mainly dependent on fossil fuels and the use of fossil fuel is the main reason for global increases of CO<sub>2</sub> amount [3]. According to global carbon emissions sources [4], carbon dioxide emissions from coal, oil, natural gas, cement, and gas flaring were 43%, 33%, 18%, 5.3%, and 0.6%, respectively in 2012. Emissions of greenhouse gases grew 2.2% per year between 2000 and 2010, compared with 1.3% per year from 1970 to 2000 [5]. The world is not capable of absorbing large amounts of CO<sub>2</sub> at the rate it is produced by fossil fuels. As a result, increasing the volume of CO<sub>2</sub> in the environment has increased global warming and further climate change. Global warming and climate changes are challenging all over the world. The use of renewable energy provides benefits that reduce emissions of air pollutants as well as greenhouse gases. Therefore, alternative sources of energy are needed so that mankind can survive on the earth without depending on fossil fuels. Solar energy is one of the renewable energy sources that will contribute to the security of future energy supplies [6,7]. Today, only 13% of energy comes from renewable sources (biofuel and waste 10%, hydro 2.3% and others: solar,

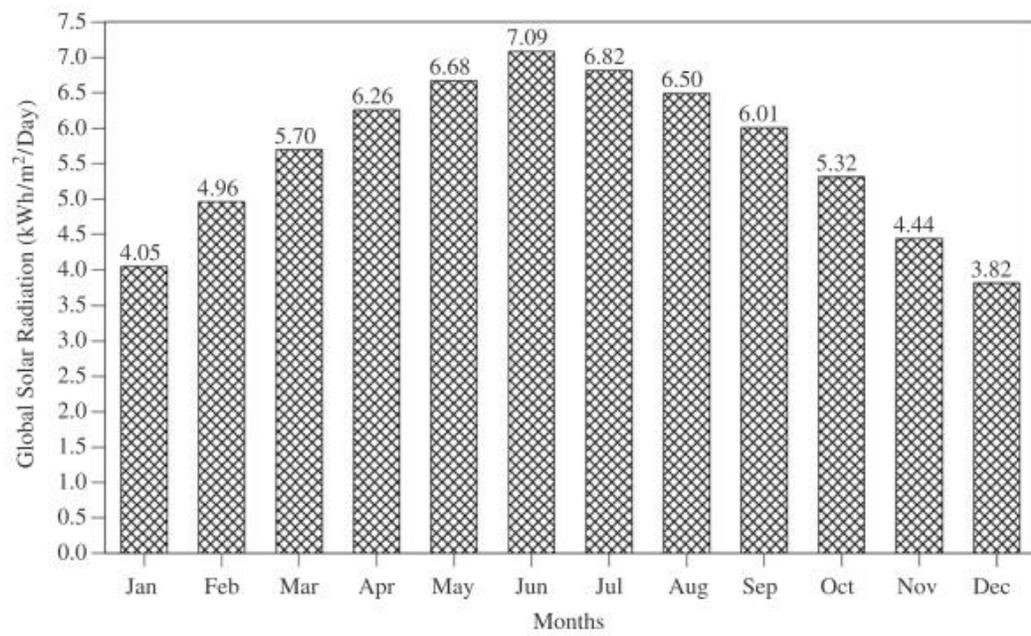

wind, geothermal, heat, among others 0.9%), 81% fossil fuels (oil 32.4%, natural gas 21.4%, and coal 27.3%), and 5.7% nuclear power. Fig. 1 shows the worldwide sources of total primary energy supply in 2010 [5].

## **1.2.Solar energy distribution in Saudi Arabia**

It is common knowledge that solar radiation is unevenly distributed, and that it varies in intensity from one geographic location to another depending upon the latitude, season, and time of day. Saudi Arabia lies between latitudes 31° N and 17.5° N and longitudes 50° E and 36.6° E. The land elevation varies between 0 and 2600 m above the mean sea level. Complex terrain is found in the southwest region of the Kingdom. The East and the West coasts of the Kingdom are located on the Arabian Gulf and Red Sea, respectively. Mainly two seasons, winter and summer, are observed during the year. The vast open land experiences high intensities of solar radiation and long hours of sunshine duration [8]. The seasonal variation of global solar radiation over Saudi Arabia is shown in Fig-2. Solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times the current energy demands [9]. Light from the sun can be harvested by dye-sensitized solar cells (DSSCs). DSSCs have attracted considerable attention due to an ideal compromise between efficiency and cost-performance [10–12]. The major component of the DSSCs is a dye. Its function is to absorb incoming sunlight and produce excitons. It is chemically bonded to the porous surface of the semiconductor.

**Fig 1.1: Shows the sources of world total primary energy supply 2010**

**Fig 1.2: Seasonal variation of global solar radiation over Saudi Arabia [8]**

### 1.3. Quantum Mechanical Modeling

We used density functional theory (DFT) and time dependent DFT quantum mechanical techniques to simulate the complex photosensitizers. For the past 30 years density functional theory has been the dominant method for the quantum mechanical simulation of periodic systems. In recent years, it has also been adopted by quantum chemists and is now very widely used for the simulation of energy surfaces in molecules [13]. The reasons for its popularity and success are

- 1) The DFT approach is in principle exact [14].
- 2) It preserves at all levels of approximation the appealing one-electron molecular orbital (MO) view on chemical reactions and properties. The computed orbitals are suitable for the typical MO-theoretical analyses and easy to understand [15].
- 3) It is a relatively efficient computational method, and its fundamental scaling properties do not deteriorate when methodological precision is increased, in particular, when a more accurate XC functional is applied [16].

#### 1.3.1. The Kohn-Sham molecular orbital (MO) model

The fundamental assumption in Kohn–Sham density functional theory (KS-DFT) is that we can use a single electron calculation to “n” interacting electrons. It can be done by applying appropriate local potential  $V_{XC}(r)$ , external potentials  $V_{ext}(r)$  and the Coulomb potential of the electron cloud  $V_C(r)$ , then using Eq. (1)

$$\left( -\frac{1}{2}\nabla^2 + V_{ext}(r) + V_C(r) + V_{XC}(r) \right) \varphi_i(r) = \varepsilon_i \varphi_i(r) \quad (1)$$

The potential  $V_{XC}$  is the functional derivative with respect to the density ( $\rho$ ) of the exchange–and–correlation energy functional  $E_{XC}[\rho]$ . The one-electron molecular orbitals (MOs)  $\phi_i$  with corresponding orbital energies  $\varepsilon_i$  define the exact electronic charge density and give access to all properties. The (first) derivatives of the energy with respect to nuclear displacements at the end of the self consistent field (SCF) method are used to find stationary points in the energy surface, particularly for the geometry optimization of molecules [13].

According to Runge-Gross theorem [17], the external potential individually finds out the density for a given interaction potential. While according to Kohn-Sham assumption the density of the non-interacting system is equal to the density of an interacting system. The benefit of this assumption is that, the wave function of a non-interacting system can be represented as a Slater determinant of single-particle orbitals, each of which are determined by a single partial differential equation in three variable. Then, the time-dependent (TD) Kohn–Sham equations are:

$$i \frac{\partial}{\partial t} \varphi_i(r, t) = \left( -\frac{\nabla^2}{2} + V[\rho](r, t) \right) \varphi_i(r, t) \quad (2)$$

$$\rho(r, t) = \sum n_j |\varphi_j(r, t)|^2 \quad (3)$$

The potential ( $V$ ) includes the  $V_C(r)$ , the nuclear potential  $V_{ext}(r)$  and  $V_{XC}$ , all are functions of time. KS-TDDFT technique with solvent effect is used to calculate the excitation energies ( $E_{ex}$ ) in DFT.

## **1.4. Thesis Summary**

This section will highlight the summary of each chapter. Each chapter will be discussed in the manuscript format.

### **Chapter-2**

Chapter-2 describes the comprehensive review on importance of solar energy and superiority of dye sensitized solar cells (DSSCs) over silicon solar cells. Solar energy is an abundant and accessible source of renewable energy available on earth, and many types of photovoltaic (PV) devices like organic, inorganic, and hybrid cells have been developed to harness the energy. PV cells directly convert solar radiation into electricity without affecting the environment. Although silicon based solar cells (inorganic cells) are widely used because of their high efficiency, they are rigid and manufacturing costs are high. Researchers have focused on organic solar cells to overcome these disadvantages, . DSSCs comprise of a sensitized semiconductor (Photoelectrode) and a catalytic electrode (counter electrode) with an electrolyte sandwiched between them and their efficiency depends on many factors. The maximum electrical conversion efficiency of DSSCs attained so far is 11.1%, which is still low for commercial applications. This chapter examines the working principle, factors affecting the efficiency and key challenges facing DSSCs.

### **Chapter-3**

This chapter describes the synthesis of 1,3,4-Oxadiazol based photosensitizers for solar cell applications. In this work, four oxadiazol based photosensitizers were synthesized by

introducing biphenyl, naphthalene, anthracene and triphenyl amin as electron-donating moieties. The electrochemical and optical properties of these sensitizers were investigated. These photosensitizers were then employed in solar cells. The UV-Visible absorption spectroscopy, photocurrent–voltage ( $I-V$ ) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize the solar cells. The results indicate that 1,3,4-Oxadiazole pi-spacer with anthracene moiety shows the highest efficiency of 2.58%. Density functional theory and time dependent density functional theory DFT/TD-DFT modeling techniques were used to compute the electronic and optical properties of sensitizers.

#### **Chapter-4**

Chapter-4 describes the fabrication of DSSCs using hybrid photoanode and  $N_3$  ( cis-diisothiocyanato-bis(2,2'-bipyridyl-4,4'-dicarboxylic acid) ruthenium(II)) sensitizer. CNTs suppress the charge recombination with electrolyte and improves the charge transport process in DSSCs. Titanium oxide/multi-walled carbon nanotubes ( $TiO_2$ /MWCNTs) photoanodes were prepared using mixing technique. Dye sensitized solar cells (DSSCs) based on  $TiO_2$ /MWCNTs composite with different concentrations of CNTs (0, 0.03, 0.06, 0.09, 0.15, 0.21 wt. %) were fabricated using  $N_3$  dye as a sensitizer. Transmission electron microscope (TEM) was used to confirm the dispersion of carbon nanotubes in  $TiO_2$ . The UV-Visible absorption spectroscopy, photocurrent–voltage ( $I-V$ ) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize device. The results show that the photo conversion efficiency is highly dependent on the concentration of CNTs in the photoanode. The solar cell based on photoanode containing 0.03 wt. % MWCNTs, has a

power conversion efficiency, which is about 30% greater than that of the unmodified photoanode.

## **Chapter-5**

This chapter describes the co-sensitization technique to enhance the efficiency of DSSCs. Co-sensitization of two or more dyes on hybrid TiO<sub>2</sub>- MWCNTs photoanode is an effective approach to enhance the performance of a dye-sensitized solar cell (DSSC). In this work, N719 sensitizer is co-sensitized with N3. It was found that the co-sensitized device showed significantly enhanced  $V_{OC}$  and  $J_{SC}$  relative to its individual single-dye sensitized devices. Upon optimization, the device made of the 0.1Mm N<sub>3</sub> + 0.4mM N719 system yielded  $J_{SC} = 12.5 \text{ mA cm}^{-2}$ ,  $V_{oc} = 0.73\text{V}$ ,  $FF = 0.45$  and  $\eta = 4.1 \%$ ; this performance is superior to that of either individual device made from N<sub>3</sub> (3.69%) and N719 (3.59 %) under the same conditions of fabrication. The overall efficiency of DSSCs was further improved to 4.46% by the incorporation of MWCNTs in TiO<sub>2</sub>. The hybrid TiO<sub>2</sub>/MWCNTs photoanodes with different concentrations of CNTs (0.04, 0.08, 0.12, 0.16 wt. %) were prepared using mixing technique. The optimized composition of N3+N719 was selected for the co-sensitization of hybrid photonodes.

## **Chapter-6**

This chapter highlights the applications of graphene in DSSCs. Composite photoanodes for dye sensitized solar cells (DSSCs) were prepared by simple addition of graphene (GR) micro-platelets to TiO<sub>2</sub> nanoparticulate paste. Transmission electron microscopy (TEM) was used to confirm the presence of graphene in composite films after heating at 450 C for 30 minutes. TiO<sub>2</sub>/graphene based DSSCs with different concentrations of

graphene were fabricated using N749 photosensitizer. The UV-Visible absorption spectroscopy, photocurrent–voltage ( $I-V$ ) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize the cells. The results indicate that graphene/TiO<sub>2</sub> photoanode improves the performance of solar cell. This is because the graphene/titania electrode accelerates electronic transportation and suppresses the charge recombination. Under an optimal conditions, solar cell based on graphene/TiO<sub>2</sub> shows power conversion efficiency (PCE) of 4.1 %, which is about 30% greater than the cell based on pristine TiO<sub>2</sub> electrode (3.16%). The objective of this study is to develop a fast, cheap, and an effective means to increase the photo conversion efficiency (PCE) of DSSCs.

## **Chapter-7**

This chapter further describes the applications of DFT/D-DFT in optimizing the complex structures of photosensitizers. Complex organic compounds with benzene/thiophene as pi-segments are inspected as photosensitizers for applications in dye sensitized solar cells. To better understand the charge transport process involved in the dye sensitized solar cells, we used the results of Kohn–Sham density functional theory and time-dependent density functional theory (DFT) studies of benzene/thiophene based sensitizers as well as the dye bound to a TiO<sub>2</sub> nano cluster. We investigated the electronic structures and UV-Vis spectra of the sensitizers alone and linked to the cluster. We also showed energy level diagrams, the major transitions of molecular orbitals and free energy calculation of the electron transfer from the sensitizer to the conduction band of the TiO<sub>2</sub>. The objective of this study is to explore the applications of DFT and time dependent DFT in the field of dye designing for solar cells.

## Chapter-8

These chapters describe the computational study of geometry and electronic structure properties of novel oxadiazole based organic sensitizers using density functional theory (DFT) and time dependent DFT (TD-DFT) modeling techniques. In this study, four photosensitizers were designed by introducing oxadiazole isomers as  $\pi$ -conjugated bridges between donor and acceptor moieties. The computational analysis was performed to investigate the key parameters of light harvesting efficiency (LHE), free energy for electron injection ( $\Delta G^{\text{inject}}$ ), excitation energies and frontier molecular orbitals (FMOs). The results suggest that the system with 1,2,3-oxadiazole shows a balance among the different crucial factors and may result in the highest incident photon to charge carrier efficiency of dye-sensitized solar cells. The dye/(TiO<sub>2</sub>)<sub>8</sub> anatase clusters were also simulated to illustrate the electron injection efficiency at the interface. Similarly, the N<sub>3</sub> (ruthenium based sensitizer) dye was simulated under the same conditions. The computation results were compared with experimental values to validate the simulation basis/assumptions.

## Chapter-9

Brief summary of the conclusion and recommendations will be presented in this chapter.

## **Abstract**

The solar energy is an abundant and accessible source of renewable energy available on earth. To bring this energy in use, many types of photovoltaic (PV) devices like organic, inorganic and hybrid cells have been developed. These PV cells directly convert the solar radiation into electricity, leaving no environmental effect. Silicon based solar cells (inorganic cells) are being widely used because of their high efficiency. But silicon PV cells are rigid and their manufacturing cost is high. To address these problems, research has focused on the organic solar cells. Dye sensitized solar cells (DSSCs) are proficient and low cost photovoltaic devices among all the organic solar cells. They consist of an electrolyte sandwiched between a sensitized semiconductor (Photoelectrode) and a catalytic electrode (counter electrode). The efficiency of DSSC depends on many factors. The electrical conversion efficiency of DSSCs has been attained to 11.1% so far. But it is still low for commercial applications. This review examines working principle, factors affecting the efficiency and key challenges of DSSCs.

**Keywords:** Solar radiation, DSSC, Photovoltaic, Semiconductor, electrolyte.

## 2.1. Introduction

The world energy demand is increasing day by day. It is expected that world power consumption will be about 23 TW (terawatts) in 2050, which is currently 13 TW [1]. Fossil fuels meet 80% of the energy requirement of the whole world. But fossil fuels are depleting rapidly [2]. Moreover, the burning of fossil fuels also raises the amount of carbon dioxide in the atmosphere. Owing to growing energy demand, exhaustion of oil resources and global warming issues, there is a need for clean and renewable energy technologies. The photovoltaic technology employing solar energy is regarded as most efficient technology among all the sustainable energy technologies such as tidal power, solar thermal, hydropower and biomass [3].

The solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times more than current energy demands [4]. To bring solar energy in use, the first practical photovoltaic cell was designed in 1954 at Bell laboratories. They used a diffused silicon p-n junction and 6% efficiency was found [5]. But now the light to electricity conversion efficiency of silicon based solar cells is between 15% and 20% [6]. Though need of high decontamination of silicon, use of toxic chemicals in their manufacturing and high cost has restricted their worldwide use. These constraints encouraged the search for environmentally friendly and low cost solar cells. In 1991, Michael Gratzel developed a new photovoltaic cell and the principle was similar to that of plant photosynthesis. This PV cell became known as DSSC. The efficiency of this cell was 7.1-7.9% [7]. DSSCs consist of an electrolyte inserted between a photoelectrode and a catalytic-electrode. The measuring parameters of DSSCs like electrical conversion efficiency ( $\eta$ ), Open circuit voltage ( $V_{oc}$ ), close circuit current density ( $J_{sc}$ ), fill factor (FF), interface charge

resistance and an incident photon to current efficiency (IPCE) depend on the morphological, spectroscopic and electrical properties of semiconductors, dyes and electrolytes respectively. DSSCs are an important type of thin film photovoltaic technology because of their low cost of manufacturing, ease of fabrication and light weight product [8,9]. In the near future, the venture of DSSCs as a competitive technology will thus be revealed. The latest efficiency of DSSC is more than 11% [10].

## **2.2. Structure and Mechanism of DSSC**

Structure and working principle of DSSC is shown in Fig 2-1. It consists of an electrolyte inserted between a photoelectrode and a catalytic-electrode. A charge separation process in DSSC consists of the following steps [3],

- i. Dye adsorbs on a thin film of semiconductor, absorbs incident solar energy. Upon absorbing energy, dye is become excited from the ground to the excited state
- ii. Due to the difference in energy levels of electronic states, electrons from the excited state are injected to the conduction band of the semiconductor. As a result dye is become oxidized.
- iii. The electrolyte in contact with dye donates electrons to dye to restore its initial state.
- iv. Electrolyte diffuses towards catalytic electrode where the reduction reaction takes place and electrolyte restores its initial state.

In addition to this forward charge transfer processes some backward charge transfer processes also occur in one complete cycle. These backward electron transfer processes drastically reduce the efficiency of DSSCs. These are

- i. Back transfer of electrons from semiconductor to the oxidized dye.
- ii. Recombination of injected electrons with electrolyte (dark current).
- iii. Transfer of electrons from dye excited state to ground state.

**In order to reduce backward transfer processes,**

- i. Charge transfer to semiconductor must occur with a quantum yield [12].
- ii. Lowest unoccupied molecular orbital (LUMO) of photosensitizer should be more negative than the conduction band of the semiconductor and highest occupied molecular orbital (HOMO) should be more positive than the redox potential of electrolyte [13].
- iii. Electron injection rate to semiconductor should be higher than the rate of decay of electrons from dye excited state to ground state [14].

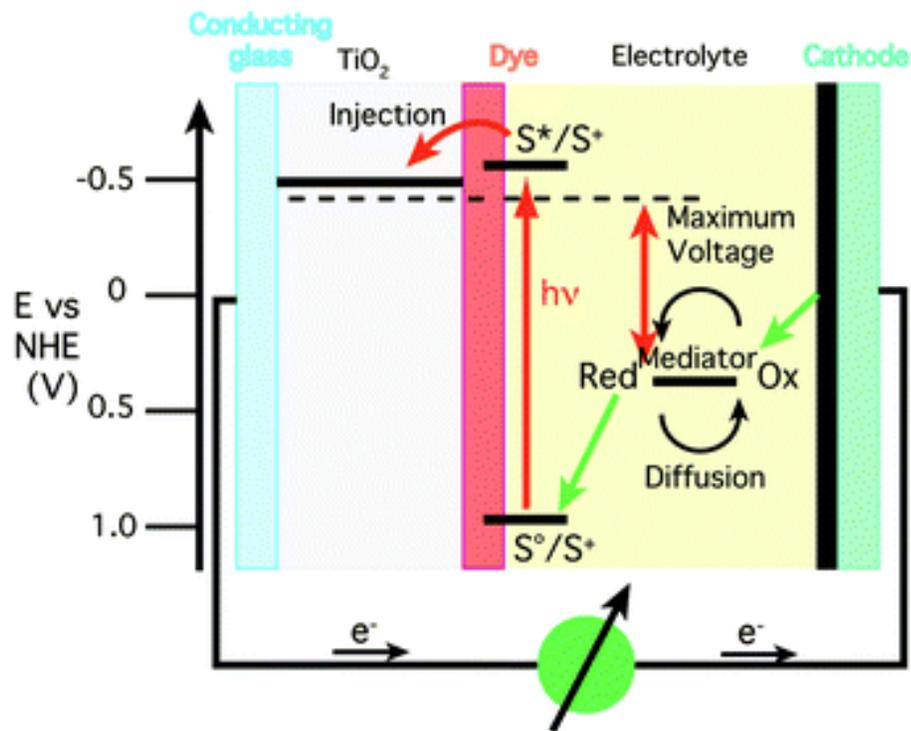

Fig 2-1: Structure and working principle of DSSC  $S^0/S^+/S^*$  = sensitizer in the ground, oxidized and excited state, respectively. Red/Ox = Redox mediator [11]

## 2.3.Components of Dye-Sensitized Solar Cell

### 2.3.1. Transparent Conductive Substrate

DSSCs are normally constructed between two sheets of conductive transparent materials. These sheets provide a space for semiconductor and catalyst deposition and also act as current collector. Substrates must be highly transparent (transparency >80%) to allow the maximum passage of sunlight to the active area of the cell. Its electrical conductivity should also be high for efficient charge transfer and minimize energy loss. These two characteristics of substrate dictate the efficiency of DSSCs [3].

FTO (fluorine tin oxide,  $\text{SnO}_2: \text{F}$ ) and ITO (indium tin oxide,  $\text{In}_2\text{O}_3: \text{Sn}$ ) are normally being used as conductive substrate. They consist of soda lime glass coated with fluorine tin oxide and indium tin oxide layers respectively. ITO films show transmittance over 80% and sheet resistance  $18\Omega/\text{sq}$ , while FTO films exhibit transmittance about 75% in the visible region and sheet resistance of  $8.5\Omega/\text{sq}$ . Siam et al have conducted the study for the comparison of FTO and ITO based DSSCs [15]. They constructed FTO and ITO based DSSCs. Photoanodes based on FTO and ITO glass substrates were sintered at  $450^\circ\text{C}$  for 2 hrs in oxygen atmosphere. They found that after sintering sheet resistance of FTO remained constant, while sheet resistance of ITO changed from  $18\Omega/\text{sq}$  to  $52\Omega/\text{sq}$ . The DSSC based on FTO has an overall  $\eta$  of 9.4% in comparison with identical cell based on ITO which has  $\eta$  of 2.4%. Thus, FTO is highly recommended for DSSCs because of its low and temperature-stable sheet resistance.

Polymers can also be used as an alternative to glass substrate because of their flexibility and low cost. Takurou et al. used PET (Polyethylene terephthalate) coated with ITO and found efficiency of 3.8% [16]. Polyethylene naphthalate (PEN) coated with ITO was used

by Rothenberger et al. and observed efficiency of 7.8% [17]. But temperature limitation restricts the use of polymers as substrate in DSSCs [18]. Metals that form a conducting layer like stainless steel, tungsten and titanium have also been used as substrates. Man Gu Kang. et al applied stainless steel and depicted efficiency of 6.1% [19]. However, the high cost and corrosion with electrolyte prohibit the use of metals as substrates [20].

### **2.3.2. Mesoporous Semiconductor**

Semiconductor provides a surface area for the dye adsorption. It accepts and conducts electrons from the excited dye to the external circuit to produce electric current [21]. The electron transport rate in the semiconductor affects the efficiency of DSSCs. It highly depends on crystallinity, morphology, and the surface area of semiconductors. Metal oxides like titanium oxide ( $\text{TiO}_2$ ), zinc oxide ( $\text{ZnO}$ ) [22] and stannic oxide ( $\text{SnO}_2$ ) [23] have been used as semiconductor materials. But experiments show that DSSCs based on  $\text{ZnO}$  and  $\text{SnO}_2$  establish lower efficiency in comparison with nanocrystalline  $\text{TiO}_2$  [23–25]. Therefore, it has been considered as an ideal semiconductor material for DSSCs since 1991 because of its better morphological and photovoltaic properties as compared to other semiconductors [26].

There are two crystalline forms of  $\text{TiO}_2$ , anatase and rutile. But the former is preferable because, anatase has high conduction band edge energy (3.2 eV) as compared to rutile (~3 eV). High band gap energy makes anatase chemically more stable [27]. An electron transport process in rutile is also slow as compared to anatase due to high packing density. Short circuit photo current of anatase based DSSC is 30% more than that of rutile based DSSC of the same film thickness. Owing to smaller surface area per unit volume, rutile absorbs less dye and therefore less efficient [28].

The main loss path in DSSCs is the recombination of injected electrons with electrolyte. This phenomenon is also called dark current and diminishes the efficiency of DSSCs. Dark current can be minimized by employing structural changes, use of insulating layers or surface treatments of TiO<sub>2</sub> [29]. Many morphologies of anatase TiO<sub>2</sub> from nanoparticles, nanofibers [30], nanowires [31], hollow sphere [32], hollow hemisphere [33], nanotubes [34] and hierarchical spheres to ellipsoid spheres [35] have been fruitfully fabricated *via* solvothermal reactions of titanium *n*-butoxide and acetic acid. The DSSC based on the hierarchical anatase TiO<sub>2</sub> sphere photoelectrode shows an overall  $\eta$  of 9.35% accompanying a  $J_{sc}$  of 17.94 mA cm<sup>-2</sup>,  $V_{oc}$  of 803 mV and FF of 0.65, which is much higher than that of nanoparticles (7.37%), nanofibers (8.15%) and ellipsoid TiO<sub>2</sub> spheres (7.93%) [36]. The substantial improvement of short- $J_{sc}$  and  $\eta$  for the hierarchical sphere-based DSSC compared to other nanostructure is mainly due to the larger dye loading, higher light scattering ability, faster charge transport and longer electron lifetime [36,37]. Another approach to minimize the charge recombination is deposition of the insulating layer on semiconductor electrode. Many metal oxide like ZnO [38], Niobium pentoxide (Nb<sub>2</sub>O<sub>5</sub>) [39], Al<sub>2</sub>O<sub>3</sub> [40] and SiO<sub>2</sub> [41] have been used as an energy barrier for retarding the charge recombination owing to their insulating properties. These insulating layers reduce the interaction between injected electron to the semiconductor and the electrolyte solution [42]. Similarly, surface treatment of TiO<sub>2</sub> with TiCl<sub>4</sub> also reduces the charge recombination process by increasing interfacial charge-transfer resistance of the TCO/electrolyte interface [43,44]. Recently, Johann Boucle synthesized Nitrogen-doped TiO<sub>2</sub> electrode (optically active electrode) by laser pyrolysis [45]. They found that the short-circuit current density of DSSC based on an N-doped

electrode increased by more than 10% compared to that of pure anatase. This progress is found to be associated with electronic and optical properties of the starting nanopowder.

### **2.3.3. Dye (Photosensitizer)**

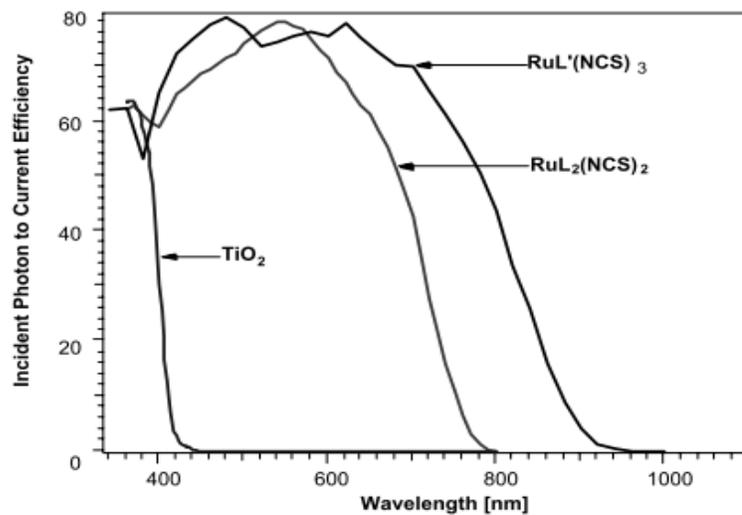

The function of dye is to absorb light and transfer electrons to the conduction band of the semiconductor. It is chemically bonded to the porous surface of the semiconductor. An efficient photosensitizer should:

- i. Show intense absorption in the visible region (400 nm-700 nm).
- ii. Be strongly adsorbed on the surface of the semiconductor.
- iii. Possess a high extinction coefficient.
- iv. Be stable in its oxidized form until it is re-reduced by an electrolyte.
- v. Be adequate for carrying out  $\sim 10^8$  turnovers without instability, which typically corresponds to the 20 years of cell operation.
- vi. LUMO of photosensitizer should be more negative than the CB of the semiconductor and redox potential of the electrolyte should be less positive than the HOMO

In addition the performance of DSSCs highly depends on a molecular structure of the sensitizers. Many chemical compounds are being used for the sensitization of semiconductor, such as the phthalocyanines [46–48], coumarin-343 [13,49,50], carboxylated derivatives of anthracene [51,52] and porphyrins [53–55]. But photosensitizers based on transition metals have been the best so far [56]. There are three classes of photosensitizer: metal complex sensitizers, metal-free organic sensitizers and natural sensitizers.

### 2.3.3.1. Metal complex sensitizers

Metal complex sensitizers consist of anchoring ligands (ACLs) and ancillary ligands (ALLs). The adhesion of photosensitizers with semiconductor is strongly dependent on the properties of ACLs. While ALLs are responsible for the tuning of the overall properties of sensitizers, the intense metal to charge transfer (MLCT) bands in the visible region is shown by polypyridinic complexes of  $d^6$  metal ions. The modification of ACLs as well as by changing the ALLs or its substituents can alter the energies of MLCT states. Many metal complex sensitizers have been prepared by changing the ALLs. However, ruthenium(II) polypyridyl complexes show better light to electricity conversion efficiency [57] because of their good spectroscopic, photostability, redox and excited state properties in the final device [58,59]. The general representation of carboxylic based sensitizers is  $[\text{Ru}(\text{dcbH}_2)_2\text{LL}']$ , while  $\text{dcbH}_2$ , and L and/or L' represent anchoring ligands and ancillary ligands, respectively. An example of high performance carboxylic based sensitizer is *cis*- $[\text{Ru}(\text{dcbH}_2)_2(\text{NCS})_2]$  also identified as  $\text{N}_3$  dye [60]. An efficient performance has also been perceived for the other ruthenium based photosensitizers such as  $[\text{Ru}(\text{tcterpy})(\text{NCS})_3]^-$  also named black dye. Fig 2-2 shows that the cell based on black dye is more proficient than red dye in the near infrared region and attained efficiency of 10.4% [4]. Record efficiencies of various sizes and their structures are shown in Table 2-1 and Fig 2-3, respectively. Although the record efficiency and stability has been achieved with ruthenium based sensitizers. But due to the high cost and scarcity of ruthenium, another course of actions should also be considered.

L = 4, 4'-COOH-2,2'-bipyridine  
 L = 4,4',4'' -COOH-2,2':6',2''-terpyridine

5	N3	2.360	8.2	0.76	15.8	71

### ***2.3.3.2. Metal-free photosensitizers***

Metal-free organic sensitizers have been fabricated not only to replace the expansive ruthenium based sensitizers but also to improve the electronic properties of devices. However, the efficiency of these sensitizers is still low as compared to ruthenium based dyes. But efficiency and performance can be improved by proper selection or tuning of the designing components. The general design mechanism of metal free organic is shown in Fig.-4. Donor and acceptors substituents are separated by  $\pi$ -conjugated spacer. The photoelectric properties of these dyes can be tuned by altering or matching different substituents within D- $\pi$ -A structure. Literature shows that efficiency of such dyes changes with the changing of the chemistry of electrolytes. For example efficiencies of metal free organic dyes in liquid, ionic and solid state electrolytes are greater than 8%, 6% and 4%, respectively [63]. These results suggest that donor groups for efficient sensitizers should be selected from the electron rich aryl amines family such as phenylamine, aminocoumarin, indoline and (difluorenyl)triphenylamine. While  $\pi$ -conjugated connector must be selected from thiophene units e.g. oligothiophenes, thienylenevinylenes, or dithienothiophene due to their outstanding charge transfer characteristics. While on the acceptor side acrylic acid group is considered as best acceptor moiety. However, the efficiency of DSSCs based on metal-free organic sensitizers is still low for industrial applications. Some important metal free photosensitizers and their photoelectric properties are summarized in Table 2-2.

Table 2-2: Metal free organic photosensitizers with different electrolytes.

Compound	$V_{oc}$	$J_{sc}$	FF [%]	$\eta$ [%]	Electrolyte*	Ref

### ***2.3.3.3. Natural Sensitizers***

Natural dyes have also been used in DSSCs because of their low cost, easy extraction, nontoxicity and environment-free threats [69]. There are two classes of plant pigments such as carotenoids and flavonoid. In addition, there are three subclasses of flavonoid: anthocyanins, proanthocyanidins and flavonols. But only anthocyanins of flavonoid group are responsible for cyanic colors ranging from salmon pink through red and violet to dark blue of most flowers, fruits and leaves. Anthocyanins are most extensively investigated as natural sensitizers and their extracts show maximum absorption in the range of 510-548 nm depending on the fruit or solvent used [70]. The basic chemical structures of most abundant anthocyanins are shown in Fig 2-5.

The length of substituent R also affects the performance of anthocyanins. If the length of R is large then performance of the dye will be less due to the steric hindrance which restricts the transfer of electrons from dye molecules to the conduction band of the semiconductor. The efficiency of natural dyes is very low because of weak interaction between semiconductor ( $\text{TiO}_2$ ) and dyes. Also, dye aggregation on nanocrystalline film is another important cause of low efficiency. Some important natural dyes and their photoelectric properties are summarized in Table 2-3. The highest efficiency has been produced by Red turnip based on the work produced by Calogero et al [71].

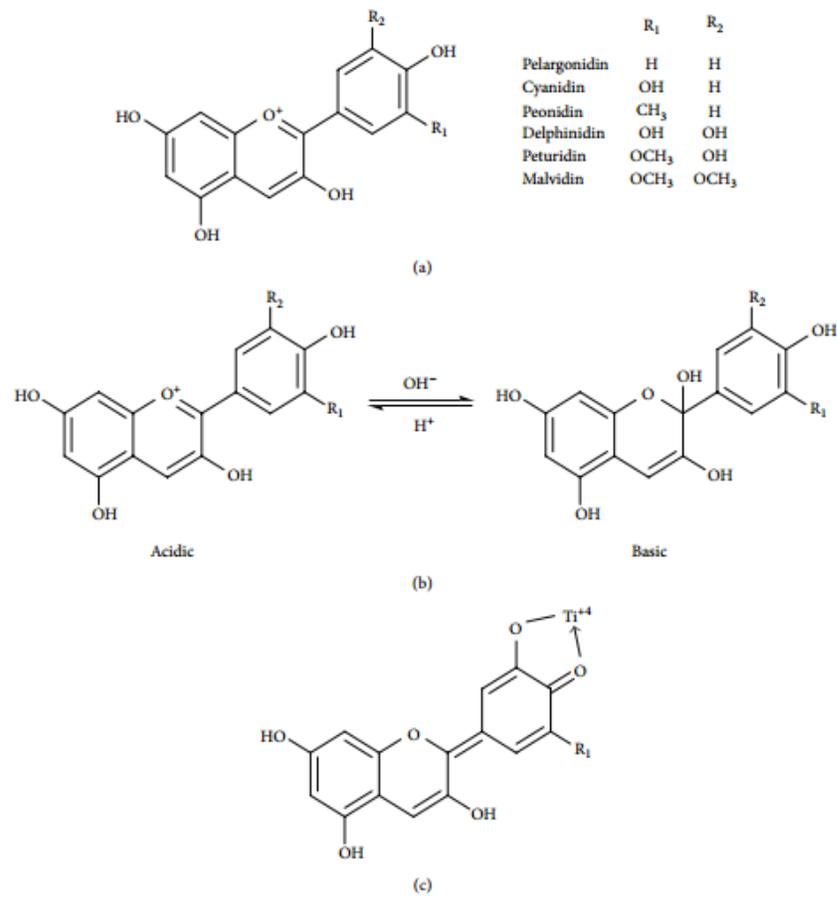

Fig 2-5: a) chemical structures of anthocyanins b) Structure in acidic and basic medium c) Chelation mechanism with TiO<sub>2</sub> [70]

#### **2.3.4. Electrolyte**

The function of electrolyte is to regenerate the dye after injecting electrons into the conduction band of the semiconductor. It also acts as a charge transport medium to transfer positive charges toward the counter electrodes. The long term stability of DSSCs depends on the properties of electrolyte. Therefore, electrolyte must hold the following characteristics [75,76],

- i. It should have high electrical conductivity and low viscosity for the faster diffusion of electrons.
- ii. It should produce good interfacial contact with nanocrystalline semiconductor and the counter electrode.
- iii. It must not cause desorption and degradation of dye from the oxidized surface.
- iv. It should not absorb light in the visible region.

Electrolytes for DSSCs are classified into three types, liquid electrolytes, solid state electrolytes and quasi-solid state electrolytes.

##### **2.3.4.1. Liquid Electrolytes**

Liquid electrolytes are further classified into two types, organic solvent electrolytes and room temperature ionic liquid electrolytes (RTIL) depending on the solvent used.

###### **2.3.4.1.1. Organic electrolytes**

Each component of organic electrolytes such as redox couple, solvent and additives affect the performance of DSSCs. The major component of organic solvents is redox couple. Many kinds of redox couples such as  $\text{Br}^-/\text{Br}_3$  [77],  $\text{SCN}^-/(\text{SCN})_2$ ,  $\text{SeCN}^-/(\text{SeCN})_2$  [78,79] and substituted bipyridyl cobalt(III/II) [80] have been investigated. But  $\text{I}_3/\text{I}$  is considered

as an ideal redox couple so far [81] because of its good solubility, rapid dye regeneration, low absorbance of light in the visible region, suitable redox potential and very slow recombination kinetics between injected electrons in semiconductor and triode ( $I_3$ ) [82].

Another basic component of liquid electrolyte is organic solvent. It is responsible for the diffusion and the dissolution of the iodide/triiodide ions. Many types of solvents such as acrylonitrile (AcN), ethylenecarbonate (EC), propylenecarbonate (PC), 3-methoxypropionitrile (MePN) and N-methylpyrrolidone (NMP) have been investigated with reliable performance [83,84]. The photoelectric performance of DSSCs depends on the donor number (DN) of the solvents. Using solvents with large DN increases the  $V_{oc}$  and decreases  $J_{sc}$  Values [85]. This is because high DN gives a lower concentration of triode which in turn reduces the dark current and therefore high photovoltage ( $V_{oc}$ ). The photovoltaic properties of DSSCs can be optimized by employing electric additives. The most efficient additives are 4-*tert*-butylpyridine (TBP), N-methylbenzimidazole (NMBI) and guanidinium thiocyanate (GuNCS) [86]. These additives are adsorbed onto the photoelectrode/electrolyte interface and prevent the recombination of injected electrons with tri-iodide ions. One important parameter is the concentration of  $I/I_3$  in the mixture when used as redox couple. If the concentration is low, then it will be difficult to maintain the required conductivity. But if the concentration is high then it will absorb light in the visible region. Therefore, the concentration of  $I/I_3$  in electrolyte must be optimized.

#### **2.3.4.1.2. Ionic electrolytes**

Although covalent electrolytes show record efficiency they have a high evaporation rate due to high volatility. High evaporation rate and leakage problem limit the long term stability of DSSCs based on covalent electrolytes. In order to minimize these problems, room temperature ionic liquids (RTIL) have been employed successfully. They are a group of organic salts consisting of cations such as pyridinium, imidazolium and anions from the halide or pseudo-halide family [87]. They act simultaneously as iodine source and as a solvent. The most commonly used IL for DSSCs applications are N, N' bis-alkyl-substituted imidazolium iodides [88]. It has been found that the viscosity of these salts decrease with decreasing alkyl chain length due to decrease of van der Waals forces. Therefore, the conductivity of IL electrolytes decreases because an increase in viscosity limits the diffusion of charges in the liquid [89]. The preferred counter ions for alkyl imidazolium based ILs are  $I^-$ ,  $N(CN)_2^-$ ,  $B(CN)_4^-$ ,  $CF_3COO)_2N^-$ ,  $BF_4^-$ ,  $PF_6^-$  and  $NCS^-$ . Instead of alkyl imidazolium based ILs, alkyl pyridinium and trialkylmethylsulfonium based ILs have also been developed for DSSCs applications. Some ILs and their efficiencies in DSSCs are presented in Table 2-4. However, low efficiency due to high viscosity limits their application as electrolytes in DSSCs.

Table 2-4: : ILs and their efficiencies in DSSC applications

No	Ionic Liquids	$\eta$ [%]	Ref
1	1-hexyl-3-methylimidazolium iodide	5.0	[89]
2	1-methyl-3-(3,3,4,4,5,5,6,6,6,-nonafluorohexyl) imidazolium	5.1	[90]
3	1-butyl-3-methylimidazolium iodide	4.6	[90]
4	S-propyltetrahydrothiophenium iodide	3.51	[91]
5	Eutectic mixture of glycerol and choline iodide	3.88	[92]

#### ***2.3.4.2. Solid-state electrolytes***

Leakage is a key problem in liquid electrolytes based DSSCs which drastically reduce the long term stability of solar cells. In order to improve the performance and stability, solid state electrolytes have been developed [2]. It is just to replace the liquid electrolyte with p-type semiconductor or hole transfer material (HTM). A band gap structure of p-type semiconductor must be compatible with the HOMO level of the photosensitizer and the conduction band of the n-type semiconductor ( $\text{TiO}_2$ ) [3]. Copper based compound such as CuI, CuBr and CuSCN have been employed as an inorganic HTM because of their good conductivity [81]. Organic HTMs have advantages over inorganic HTMs because of their low cost and easy deposition. The pioneer element of this class was 2,2',7,7'-tetrakis (N,N-di-pmethoxyphenylamine) 9,9'-spirobifluorene (OMeTAD) having efficiency of 0.74% (under white-light illumination of  $4\text{mW}/\text{cm}^2$ ) only [93]. Its efficiency was increased to 3.2% by improving dye adsorption in the presence of silver ions in the dye solution [94]. Solid state electrolytes based DSSCs have very low light-to-electricity conversion efficiency due to poor intimate contact between photoelectrode-HTMs and high rate of charge recombination from semiconductor to HTM. However, light-to-electricity conversion efficiency can be improved by introducing a redox couple into solid state electrolyte as a transport medium. Some common HTMs and their efficiencies in DSSCs are presented in Table 2-5.

Table 2-5: Performance of different HTMs in DSSCs.

No	HTMs	$\eta$ /%]	Ref
1	CuI	2.4	[95]
2	CuI	3.8	[96]
3	CuSCN	1.5	[97]
4	Spiro-OMeTAD	3.2	[94]
5	Polyaniline	1.15	[98]

#### ***2.3.4.3. Quasi-solid state electrolytes***

Though, leakage problem is solved by solid state electrolytes. But intimate contact between mesoporous semiconductor and HTM is still a problem. Since solid-state electrolytes do not penetrate into the pores of the semiconductor. This problem has been solved by quasi-solid state electrolytes. Quasi-solid state electrolyte is a composite of polymer and liquid electrolyte [99,100]. Because of the unique network structure of polymers, quasi-solid state electrolytes show better long term stability, high electrical conductivity and good interfacial contact as compared to liquid electrolytes [99,100]. The conductivity of the quasi-solid state electrolytes depends on the molecular weight and the morphology of the polymer because the higher mobility of charges occurs in the amorphous phase of polymer than in the crystalline phase. The performance of polymer electrolytes based DSSCs strongly depends on the working temperature. This is because an increase of temperature causes the phase transformation from a gel state to solution state [81]. Some important polymer electrolytes and their performance are summarized in Table 2-6.

Table 2-6: Polymer electrolytes and their performance in DSSC applications

No	Polymer	Solvent	$\eta$ [%]	Ref
1	1,3:2,4-Di- <i>O</i> -benzylidene-D-sorbitol	3-methoxypropionitrile	6.1	[100]
2	5 poly (acrylic acid)-poly(ethylene glycol)	<i>N</i> -Methyl-2-pyrrolidone+ $\gamma$ -butyrolactone	6.1	[101]
3	Low molecular weight gelator	1-hexyl-methylimidazoliumiodide, iodine	5	[89]
4	poly(acrylonitrile- <i>co</i> -styrene)	4- <i>tert</i> -butylpyridine+NaI+I <sub>2</sub>	2.75	[102]
5	poly(ethylene glycol) (PEG)	propylenecarbonate+potassium Iodide, Iodine	7.2	[103]
6	poly(ethylene oxide- <i>co</i> -propylene oxide)trimethacrylate	EC +GBL	8.1	[104]
7	poly(vinylidene-fluoride- <i>co</i> -hexafluoropropylene)	1,2-dimethyl-3-propylimidazoliumiodide,iodine	>6	[105]

### **2.3.5. Counter electrode**

Counter electrode is used for the regeneration of the electrolyte. The oxidized electrolyte diffuses toward the counter electrode where it accepts electron from the external circuit. A catalyst is needed to accelerate the reduction reaction. Platinum (Pt) is considered as a preferred catalyst because of its high exchange current density, good catalytic activity and transparency. The performance of CE depends on the deposition method of Pt on TCO substrate. Many deposition methods like thermal decomposition of hexachloroplatinic salt in isopropanol [106], electrodeposition [107], sputtering [108], vapor deposition and screen printing [109]. It has been found that characteristics of Pt catalyst decrease with time in the presence of iodide/tri-iodide redox couple [110]. Experiments show that two major factors are responsible for the adulteration of Pt counter electrode: alteration of its electrocatalytic properties and annihilation of Pt from the substrate [106]. Although the Pt catalyst possesses high catalytic activity, the high cost of Pt is a disadvantage. Therefore, grapheme and conductive polymers have also been used as alternative materials for counter electrode .But their electrical efficiencies were very low when compared to the Pt catalyst.

### **2.4. Key challenges and recommendations**

Low efficiency and low stability are the major challenges for the commercial growth of DSSCs. The following factors are responsible for the low efficiency and stability of DSSCs:

- i. Non-optimized dark current
- ii. Poor performance of dyes in the NIR region

- iii. Poor contact between the electrodes
- iv. High volatility and high viscosity of electrolytes
- v. Degradation of electrolyte properties due to UV absorption of light

Following steps can be recommended in order to enhance the efficiency and stability of DSSCs,

- i. Improvement in the morphology of semiconductors to reduce dark current
- ii. Improvement in the dye design to absorb light NIR region
- iii. Develop low volatile and less viscous electrolyte to improve the charge transfer rate.
- iv. Improvement in mechanical contact or adhesion between the two electrodes
- v. Use of additives for dyes and electrolytes that enhance their properties.

However the efficiency and stability of DSSCs do not depend on a single factor. There must be traded off among different factors to improve the performance of DSSCs.

## **2.5. Acknowledgments**

The authors would like to acknowledge the support provided by King Abdulaziz City for Science and Technology (KACST) through the Science & Technology Unit at King Fahd University of Petroleum & Minerals (KFUPM) for funding this work through project 11-ENE1635-04 as part of the National Science, Technology, and Innovation Plan. KFUPM is also acknowledged for supporting this research. The authors would like to acknowledge the Center of Research Excellence for Renewable Energy at KFUPM.

**This chapter has been submitted in journal of “*Synthesis*”**

## **Abstract**

1,3,4-Oxadiazol based photosensitizers were synthesized for solar cell applications. In this work, four oxadiazol based photosensitizers were synthesized by introducing biphenyl, naphthalene, anthracene and triphenyl amin as electron-donating moieties. The electrochemical and optical properties of these sensitizers were investigated .These photosensitizers were then employed in solar cells. The UV-Visible absorption spectroscopy, photocurrent–voltage ( $I-V$ ) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize the solar cells. The results indicate that 1,3,4-Oxadiazol pi-spacer with anthracene moiety shows the highest efficiency of 2.58%. Density functional theory and time dependent density functional theory DFT/TD-DFT modeling techniques were used to compute the electronic and optical properties of sensitizers.

**Keywords:** 1,3,4-Oxadiazol, electron-donating moieties, efficiency, Density functional theory

### 3.1. Introduction

Inorganic silicon based solar cells are being currently used for the conversion of photo energy on a commercial scale because of their high efficiency [1]. However, the need of highly purified silicon, use of toxic chemicals in their manufacture, and the high cost has restricted their worldwide use. These constraints encouraged the search for low cost and environmentally friendly solar cells. In this context, dye-sensitized solar cells (DSSCs) have received widespread attention in recent years because of their ease of processing and the low cost [2-7].

Dye is the major component of DSSCs, which absorbs incoming sunlight and produce excitons [8, 9]. The photosensitizer, which is chemically bonded to the porous surface of the semiconductor, can be a metal complex or a metal-free organic sensitizer. But metal free organic photosensitizers are preferred over ruthenium based sensitizers because of their low cost and good transport properties. The basic structural unit of metal-free dyes is the donor- $\pi$ -spacer-acceptor (D- $\pi$ -A) unit and the photovoltaic properties of such dyes can be fine tuned by selecting suitable groups within the D- $\pi$  -A structure [10]. These results suggest that the donor groups to form efficient sensitizers should be selected from the electron rich aryl amines family including phenylamine, aminocoumarin, indoline, and (difluorenyl)triphenylamine [8]. Many organic groups have been used as  $\pi$ -spacer to tune the electrical and optical properties of light sensitive materials [11]. The best known organic compounds for obtaining such properties are porphyrins [12], styrylarylenes [13], perylenes [14], benzofurans [15], indoles [16], thiazole [17, 18] and oxadiazole [19]. Among them, the oxadiazole derivatives are considered the most efficient electron transport materials owing to their good thermal and chemical stabilities and high quantum

yield [20]. Many studies have shown that 2-(4-biphenyl)-5-(4-tertbutylphenyl)-(1, 3, 4) oxadiazole exhibits excellent charge transport properties [19, 21-24]. Tian and co-workers successfully synthesized the naphthalimide derivatives containing the oxadiazole moiety. They found that oxadiazole moiety increases the electron injection properties and minimizes the carrier recombination [21].

The density functional theory (DFT) and time-dependent DFT (TD-DFT) can provide a deeper understanding of the relationship between molecular structure and properties of compounds. Thus, theoretical calculations are important to design new and efficient dyes for DSSCs [25-32]. DFT is used because it is the only ab initio method able to do the calculation at a cost acceptable for routine use. Here, the aim is to study the theoretical and experimental studies of novel oxadiazole based organic dyes and establish their structure-performance relationship for application in DSSCs.

### **3.2. Computational Detail**

All the DFT/TD-DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01). BAND mode was used to simulate the anatase TiO<sub>2</sub> cluster. Here, we selected tetragonal anatase crystal structure with single layer (001) surface slab. Then, a 4×1 supercell was created from this slab. All atoms were mapped within the unit cell. The ground state geometries of oxadiazole dyes were optimized by applying generalized gradient approximation (GGA) at OLYP. The (TiO<sub>2</sub>)<sub>8</sub> nano-particle cluster was also simulated by considering GGA at Becke, parameter, Lee-Yang-Parr (BYLP) level with triple- $\zeta$  polarization basis function. In all the calculations, the relativistic effects were taken into account by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

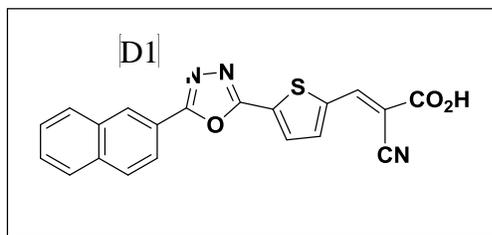

### **3.3. Experimental and Characterization**

#### **3.3.1. Designed system**

The structures and names of new class of dyes are shown in Fig. 1. In these structures, biphenyl, naphthalene, anthracene and triphenyl amin were used as the electron-donating moiety and carboxyl and cyano groups (-COOH and -CN) were introduced as the electron acceptor and the anchor group because of their high electron-withdrawing ability and strong bonding to the semiconductor. 1,3,4-Oxadiazole was used as the  $\pi$ -conjugation system, which bridges the donor-acceptor systems. A double bond and a thiophene unit were also introduced to the pi-conjugation system to fine tune the planar molecular configuration and to broaden the absorption spectra. The performance of the dyes was tested with different isomers of oxadizoles as the  $\pi$ -conjugated bridge.

#### **3.3.2. Fabrication of DSSCs**

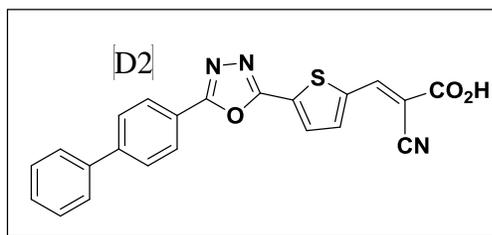

A 2 mM solution of each dye was prepared in methanol. The composite electrodes were soaked in the dye solution for 24 hours. After sensitization, the samples were washed with ethanol to eliminate unanchored dye. Then, DSSCs were fabricated employing the sensitized hybrid anode, platinum deposited counter electrode (Plasticol T, Solaronix), 60  $\mu\text{m}$  sealing spacer (Meltonix 1170, Solaronix) and  $\text{I}^-/\text{I}_3^-$  redox couple electrolyte prepared in methoxypropionitrile with a 50 mM redox concentration (Iodolyte Z-50, Solaronix).

### 3.3.3. Characterization of DSSCs

The visible spectra of dyes in methanol and anchored to TiO<sub>2</sub> films at glass substrates were recorded with JASCO-670 UV/VIS spectrophotometer. Keithley 2400 Source Meter was used to measure the  $I-V$  characteristics of the DSSCs using IV-5 solar simulator (Sr #83, PV Measurement, Inc) at AM1.5G (100 mWcm<sup>-2</sup>). The silicon solar cell was used as a reference for calibration. The impedance spectroscopy (EIS) was measured in dark conditions of illumination via Bio-Logic SAS (VMP3, s/n:0373), with an AC signal of 10 mV in amplitude, in the frequency range between 10 Hz and 500KHz.

## 3.4. Results and Discussion

### 3.4.1. Energy levels of photosensitizers

The HOMOs, LUMOs, and the band gap energies of the photosensitizers play an important role in providing the thermodynamic driving force for the electron injection. For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. We used a DFT technique to find the band gap of TiO<sub>2</sub> and novel photosensitizers. The electron distribution of the HOMOs and LUMOs of D1, D2, D3 and D4 are shown in Fig.2. Clearly, the HOMOs of these compounds are the highest electron density located at donor moieties. The LUMOs are located in the anchoring group through the pi-bridge. Thus, the HOMO-LUMO excitation induced by light irradiation could move the electron distribution from the donor moieties to the anchoring unit through the pi-bridge segment. The interface between the sensitizer and TiO<sub>2</sub> plays an important role in the electron injection efficiency. Though (TiO<sub>2</sub>)<sub>n</sub> clusters

(n = 4, 6, 8) were simulated, (TiO<sub>2</sub>)<sub>8</sub> containing model was selected because of its balanced electronic properties (conduction band ~ -4.0 eV and band gap 3.18 eV).

Table-1 shows that the HOMO levels of the dyes are in the order of D3 (-4.689) > D4 (-5.180) > D1 (-5.657) > D2 (-5.682). While, LUMOs energy levels are in the order of D3 (-3.694) > D4 (-3.840) > D2 (-3.867) > D1 (-3.956). The electron donating moieties significantly affect the HOMO and LUMO energy levels of the dyes. Similarly, the H-L<sub>gap</sub> of the dyes are in the order of D3 (1.175) < D4 (1.340) < D1 (1.701) < D2 (1.815). These results suggest that dyes 1-4 can inject electrons to the conduction band of titanium oxide.

Table 3-1: The frontier molecular orbital (eV) and H-L<sub>gap</sub> (eV) energies of systems 1-4

<b>Dyes</b>	<b>LUMOs (eV)</b>	<b>HOMOs (eV)</b>	<b>Band Gap (eV)</b>
D1	-3.956	-5.657	1.701
D2	-3.867	-5.682	1.815
D3	-3.694	-4.869	1.175
D4	-3.840	-5.180	1.340

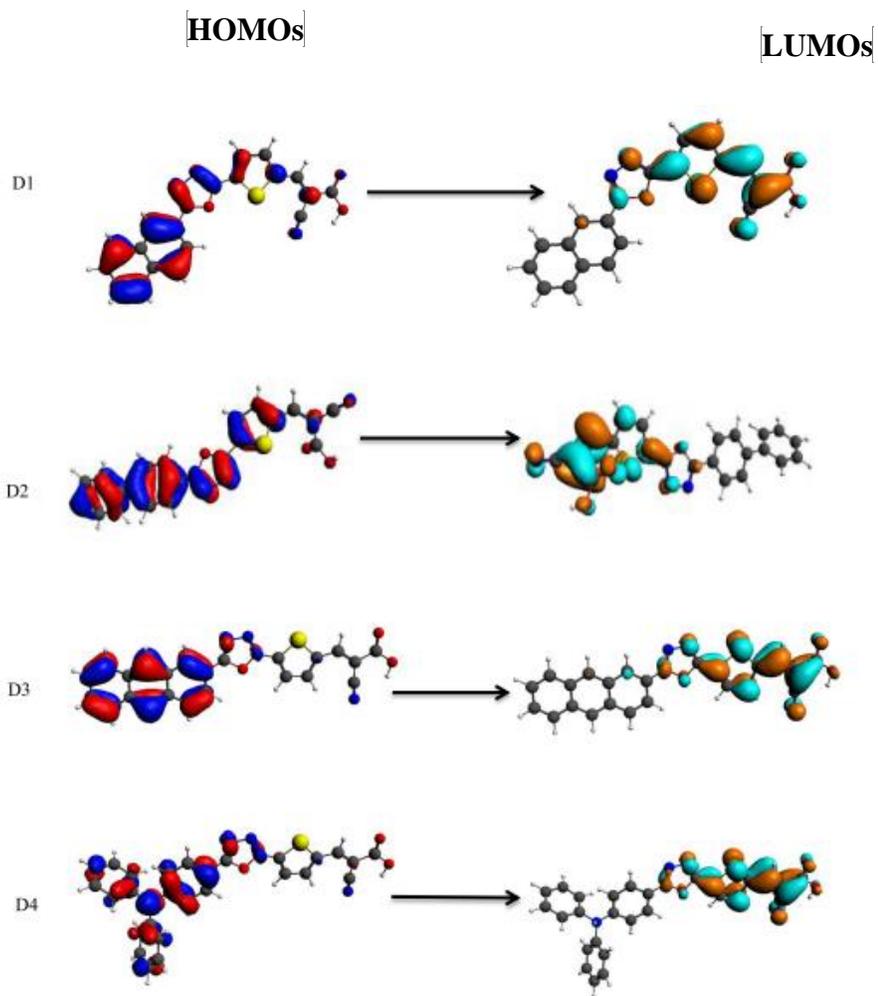

Fig 3-2: Simulated HOMOs and LUMOs of dyes

### 3.4.2. Optical properties

The UV-Vis absorption spectra of D3 in chloroform and adsorbed on TiO<sub>2</sub> are shown in Fig 3. Two distinct absorption bands of D3 in chloroform can be observed: one relatively weak band is in the region (380-400 nm) corresponding to the  $\pi$ - $\pi^*$  electron transitions of the conjugated molecules and the other is around 430-460 nm that can be assigned to an intramolecular charge transfer (ICT) between electron-donor and electron acceptor anchoring moieties. However, the absorption shifts to lower energy values when anchored to TiO<sub>2</sub>. This is due to the fact that on the electrode the carboxylate groups bind to the TiO<sub>2</sub> surface in which Ti<sup>4+</sup> acts as proton. The interaction between the carboxylate group and the surface Ti<sup>4+</sup> ions may lead to increased delocalization of the  $\pi^*$  orbital. The energy of the  $\pi^*$  level is decreased by this delocalization, which explains the red shift for the absorption spectra.

### 3.4.3. Photovoltaic performance

Typical solar cells, with an effective area of 0.35 cm<sup>2</sup> are fabricated using D1, D2 D3 and D4 dyes. Short-circuit current density ( $J_{sc}$ ), open circuit voltage ( $V_{oc}$ ), fill factor (FF), and photovoltaic conversion efficiency ( $\eta$ ) of DSSCs are listed in Table-2 and the corresponding photocurrent evoltage ( $I$ - $V$ ) curves are showed in Fig-4. Among the four dyes, the D3-sensitized cell exhibited the best photovoltaic performance. Based on these parameters, the electron-donating ability of the donor in a dye molecule plays a key role. The electron-donating ability of donor groups is indicated by the LUMOs energy levels. Higher HOMO and LUMO energy levels of D3 do not only generate charge separation, but also accelerate the dye regeneration via fast oxidation of tri-iodide by oxidized dyes,

to avoid charge recombination between oxidized dyes and photo-injected electrons in the TiO<sub>2</sub> film, thus enhancing the sensitized cell performance.

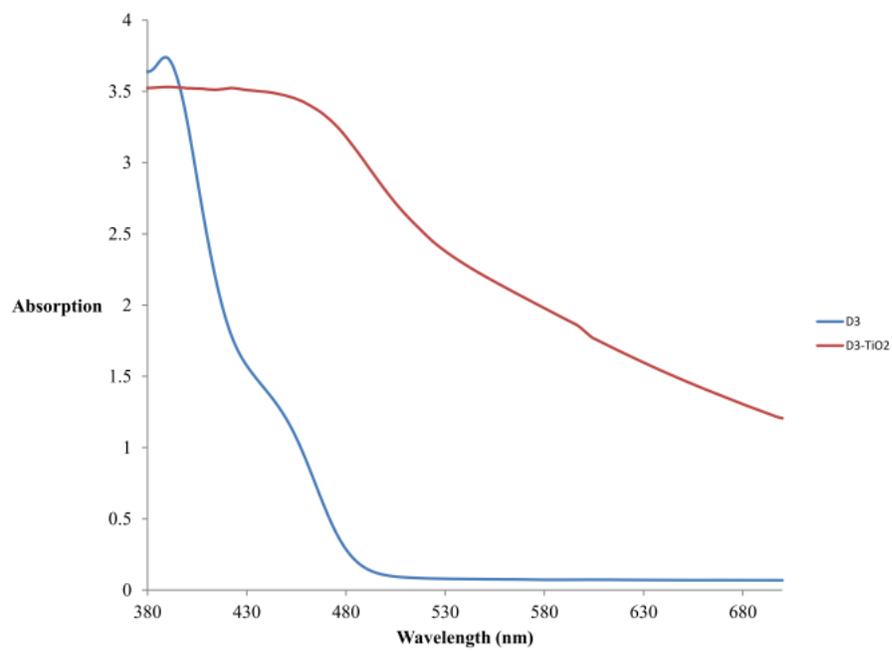

Fig 3-3: UV-Vis absorption spectrum of D3 in chloroform and anchored to TiO<sub>2</sub>

Table 3-2: Photovoltaic properties of DSSCs based on hybrid anodes

Dye	$j_{sc}$ (mA/cm <sup>2</sup> )	$V_{oc}$ (mV)	FF(%)	$\eta$ (%)
D1	0.479	448	50	0.11
D2	0.952	455	51	0.23
D3	8.178	632	50	2.58
D4	2.196	587	40	0.52

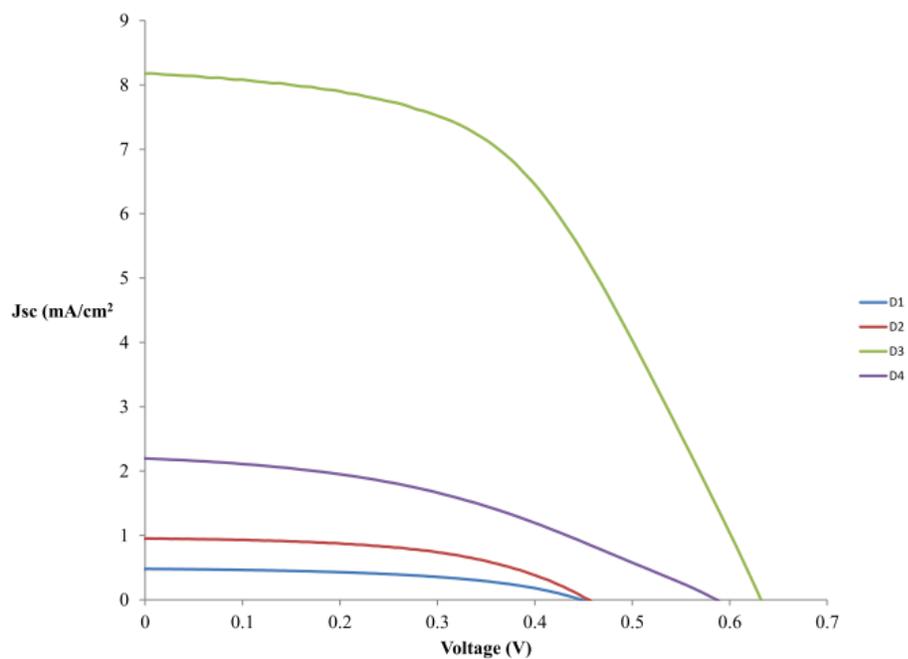

Fig 3-4: Current – voltage curves of DSSCs

#### 3.4.4. Electrochemical impedance spectroscopy (EIS) analysis

EIS analysis is performed to further elucidate the photovoltaic properties. Figure 5 shows the Nyquist plot of DSSCs which were assembled with TiO<sub>2</sub>-SQ2 and 0.06%MWCNTS-TiO<sub>2</sub>-SQ2. Generally, a normal impedance spectrum of DSSCs is represented by three arcs (semicircles). The first semicircle represents the charge transport resistance at counter electrode/electrolyte ( $R_1$ ), second signifies the charge transport resistance at the photoanode / electrolyte interface ( $R_2$ ), and third indicates the diffusion process of  $\Gamma/I_3^-$  redox couple in electrolyte ( $Z_w$ ) [33, 34]. Only second arc comes out in the Nyquist plot in the Fig 5. It is probable that the other two arcs corresponding to  $R_1$  and  $Z_w$  are overshadowed by large semicircle representing  $R_2$  [35, 36]. The  $R_2$  is related to the charge recombination rate, e.g., a smaller  $R_2$  indicates a faster charge recombination. The  $R_2$  value for DSSC assembled with D3 is greater than that of D1, D2 and D4. The higher  $R_2$  of D3 relative to D1, D2 and D4 could be attributed to the steric hindrance of bulky antherence unit.

#### 3.5. Conclusion

A series of novel dyes D1, D2, D3 and D4 have been prepared for dye sensitized solar cells (DSSCs). The results indicate that the donor moiety in organic dyes strongly influences the performance of DSSCs. The incorporation of antherence unit as a donor moiety improves the efficiency of DSSC as compared to other donor units i.e. biphenyl, naphthalene and triphenylamine. Among the four photosensitizers synthesized, maximum efficiency of 2.58% was obtained with a DSSCs based on D3 ( $J_{sc} = 8.178 \text{ mA/cm}^2$ ,  $V_{oc} = 632 \text{ Mv}$ ,  $FF = 0.5$ ). These results advocate that the photosensitizers based on antherence unit are auspicious candidates for DSSCs.

## **Abstract**

Titanium oxide/multi-walled carbon nanotubes (TiO<sub>2</sub>/MWCNTs) photoanodes were prepared using mixing technique. Dye sensitized solar cells (DSSCs) based on TiO<sub>2</sub>/MWCNTs composite with different concentrations of CNTs (0, 0.03, 0.06, 0.09, 0.15, 0.21 wt. %) were fabricated using N<sub>3</sub> dye as a sensitizer. Transmission electron microscope (TEM) was used to confirm the dispersion of carbon nanotubes in TiO<sub>2</sub>. The UV-Visible absorption spectroscopy, photocurrent–voltage (*I–V*) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize device. The results show that the photo conversion efficiency is highly dependent on the concentration of CNTs in the photoanode. The solar cell based on photoanode containing 0.03 wt. % MWCNTs, has a power conversion efficiency, which is about 30% greater than that of the unmodified photoanode. We also used density functional theory (DFT) quantum modeling technique to investigate the thermodynamic aspects of the charge transport processes involved in DSSC. Our simulation outcomes support the experimental results.

**Keywords:** Hybrid, DSSC, MWCNTs, density functional theory

#### 4.1. Introduction

The world energy demand is continually increasing and the world power consumption, which is 13 terawatts (TW) currently, is expected to reach about 28 TW in 2050 [1]. Fossil fuels, which are depleting rapidly, meet 80% of the energy requirement of the whole world [2]. Moreover, the burning of fossil fuels raises the amount of carbon dioxide in the atmosphere. Owing to growing energy demand, exhaustion of oil resources, and global warming issues, there is a need for clean and renewable energy technologies. Photovoltaic technology employing solar energy is regarded as the most efficient technology among all the sustainable energy technologies such as tidal power, solar thermal, hydropower, and biomass [3]. The solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times the current energy demand [4]. Therefore, the conversion of photo energy into electrical energy is generally considered as the most potential way to resolve the world energy crisis, owing to its huge reserves.

DSSCs have got global attention in the past fifteen years owing to their easy processing and low production cost compared with inorganic solar cell. Meanwhile, the CNTs are also being extensively explored and employed due to their excellent morphological and electrical properties. These two apparently discrete inventions (DSSCs and CNTs) were fortuitously linked together in 1991. In this year, Grätzel devised dye sensitized solar cell [5] while Iijima discovered CNTs [6]. Fortunately, both innovations were reported by the top scientific journal *Nature*.

The major component of the DSSCs is a dye. Its function is to absorb incoming sunlight and produce excitons. It is chemically bonded to the porous surface of the semiconductor. Presently, ruthenium(II)-polypyridyl complexes based DSSCs have got overall power conversion efficiencies (PCE) over 11% under standard (Global Air Mass 1.5)

illumination [7–9]. The high efficiencies of the ruthenium (II) -polypyridyl DSSCs can be attributed to their wide absorption range, good spectroscopic and photostability in the final device. In addition, the carboxylate groups attached to the bipyridyl moiety lower the energy of the ligand  $\pi^*$  orbital. The general representation of carboxylic acid based sensitizers is  $[\text{Ru}(\text{dcbH}_2)_2\text{LL}']$ , while  $\text{dcbH}_2$ , and L and/or L' represent anchoring ligands and ancillary ligands, respectively. An example of a high performance carboxylic acid based sensitizer is *cis*- $[\text{Ru}(\text{dcbH}_2)_2(\text{NCS})_2]$ , which is also known as the  $\text{N}_3$  dye. Similarly, there are two crystalline forms of  $\text{TiO}_2$ , anatase and rutile, the former is preferred because the exciton mobility in rutile is less than in anatase due to the high packing density.

However, the efficiency of DSSC is still low compared with the silicon solar cells due to recombination of injected electrons with the electrolyte (dark current) and oxidized dye [10]. Therefore, in order to improve the PCE of DSSCs, there is need to reduce the charge recombination and accelerate the electron transport [11]. Since CNTs show outstanding electrical conductivity [12–14], their incorporation in photanode may enhance the PCE of DSSCs by reducing the charge recombination.

Here, we also employed DFT and time dependent DFT to investigate the thermodynamic aspects of charge transport processes involved in DSSC. It is an effective tool as compared to other high level quantum approaches because the computed orbitals are suitable for the typical MO-theoretical analyses and interpretations [15]. Many theoreticians have successfully applied this technique to calculate the electronic structure properties of photosensitizers [15–21].

## 4.2. Computer simulations

All the DFT/TD-DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01).

### 4.2.1. TiO<sub>2</sub> cluster Model

BAND mode was used to simulate the anatase TiO<sub>2</sub> cluster. Here, we selected tetragonal anatase crystal structure with single layer (001) surface slab. Then, we created 4×1 supercell from this slab. All atoms were mapped within the unit cell.

### 4.2.2. Simulation Method

TiO<sub>2</sub> and carbon doped TiO<sub>2</sub> models were simulated by considering generalized gradient approximation (GAD) at BYLP level and triple- $\zeta$  polarization basis function. The ground state geometries of N<sub>3</sub>, N<sub>3</sub>-TiO<sub>2</sub>, N<sub>3</sub>-(TiO<sub>2</sub>-C) systems were optimized by applying a hybrid B3LYP level together with triple- $\zeta$  polarization basis function. UV-Vis spectra of N<sub>3</sub> was simulated in ethanol solvent. Here the conductor-like screening model (COSMO) was selected to take the solvent effects into account. While the excitation energies were examined using TD-DFT and statistical average of orbital potentials (SAOP) model including the solvation effects. Eighty singlet-singlet transitions were calculated, which are sufficient to fully define the whole absorption spectrum. In all the calculations, the relativistic effects were taken into account by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

Light harvesting efficiency (LHE) [22] and free energy of electron injection ( $\Delta G^{\text{inject}}$ ) [20] can be calculated by the following relations:

$$\text{LHE} = 1 - 10^{-A} \quad (1)$$

“A” represents the absorption

$$\Delta G^{\text{inject}} = E_{\text{OX}}^{\text{dye}*} - E_{\text{CB}} \quad (2)$$

$E_{\text{CB}}$  is the conduction band of the semiconductor and  $E_{\text{OX}}^{\text{dye}*}$  is the dye excited state potential, which is related as [17]:

$$E_{\text{OX}}^{\text{dye}*} = E_{\text{OX}}^{\text{dye}} - \Delta E \quad (3)$$

Similarly  $E_{\text{OX}}^{\text{dye}}$  shows the dye ground state potential and  $\Delta E$  is the minimum energy of absorption associated with  $\lambda_{\text{max}}$ , While [18]

$$E_{\text{OX}}^{\text{dye}} = -\text{HOMO} \quad (4)$$

### 4.3.Experimental

#### 4.3.1. Preparation of hybrid photoanodes

A suspension solution of ethanol and MWCNTs was prepared by dissolving 0.01g of MWCNTs in 20 ml ethanol solution. It was then sonicated for 4hr to attain a good dispersion of MWNTs in ethanol. An exact quantity of dispersed MWCNTs was mixed with known amount of anatase  $\text{TiO}_2$  paste (T/SP **14451**, solaronix) to obtain a composite paste. Five different samples of  $\text{TiO}_2$ -MWCNTs were prepared by varying the composition of MWCNTs i.e. 0, 0.03, 0.06, 0.09, 0.15, 0.21 wt. %. The  $\text{TiO}_2$ -MWCNTs paste was then tape casted on FTO glass substrate (2 mm,  $7\Omega/\text{sq}$ , solaronix ). The coated glass substrate annealed at  $450^\circ\text{C}$  for 30 min. Other photoanodes were prepared via the same process. The thickness of each photoanode was found by using cross sectional images obtained from SEM (JEOL, 6610LV). The average thickness of each film was 22  $\mu\text{m}$ .

### 4.3.2. DSSCs Fabrication and characterization

0.5 mM solution of N<sub>3</sub> (Ruthenizer-535, solaronix) dye was prepared in methanol. The hybrid electrodes were soaked in the dye solution for 24 hours. After sensitization, the samples were washed with alcohol to eliminate unanchored dye. Then, DSSCs were fabricated employing the sensitized hybrid anode, platinum deposited counter electrode (Plasticol T, solaronix), 60 μm sealing spacer (Meltonix 1170, solaronix) and I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple electrolyte prepared in methoxypropionitrile with a 50 mM redox concentration (Iodolyte Z-50, solaronix).

The UV-Vis spectra of N<sub>3</sub> in ethanol and adsorbed on TiO<sub>2</sub> films at glass substrates were recorded with an Ocean Optics ISS-UV/VIS spectrophotometer. Keithley 2400 Source Meter was used to measure the *I-V* characteristics of the DSSCs using IV-5 solar simulator (Sr #83, PVmeasurement, Inc) at AM1.5G (100 mWcm<sup>-2</sup>). The silicon solar cell was used as a reference for calibration. The impedance spectroscopy (EIS) was measured in dark conditions of illumination via Bio-Logic SAS (VMP3, s/n:0373), with an AC signal of 20 mV in amplitude, in the frequency range between 10 mHz and 1MHz. The applied bias was between 0 mV and 800 mV above the V<sub>oc</sub> of the DSSC.

### 4.4. Results and Discussion

The dispersion of MWCNTs in TiO<sub>2</sub> was ensured by TEM (JEOL, JEM-2100F) analysis. TiO<sub>2</sub>-MWCNT sample having 0.15% CNT was selected for TEM analysis. It was difficult to obtain TEM images of dispersed MWCNTs in TiO<sub>2</sub> from low concentration samples. Fig 4-1 (a) shows the anatase TiO<sub>2</sub> nanoparticles, while, Fig 4-1 (b) shows that MWCNTs randomly distributed in TiO<sub>2</sub>. The interface connection between MWCNTs and TiO<sub>2</sub> can clearly be observed, indicating that TiO<sub>2</sub> nanoparticles were well attached on

the surface of the MWCNTs. The diameter of the coated MWCNTs significantly increases and consequently the inner core of MWCNTs is hardly visible, shown in Fig 4-1 (c, d).

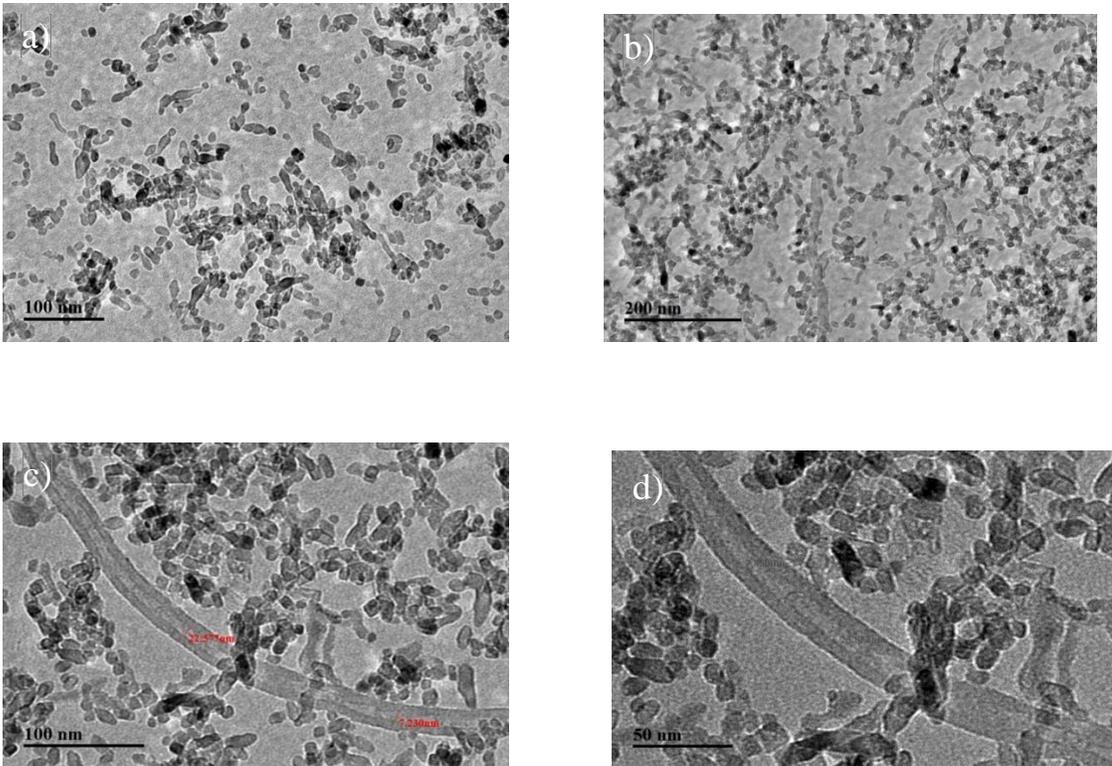

Fig 4-1: *Transmission electron microscope* images of a 0.15 % sample at various magnifications (a) Pure TiO<sub>2</sub> b) Dispersion of MWCNTs in TiO<sub>2</sub> c) Dispersion of single MWCNT in TiO<sub>2</sub> at 100 nm and d) 50 nm

The HOMOs, LUMOs and band gap energies of photosensitizers play an important role in providing the thermodynamic driving force for the electron injection to conduction band of TiO<sub>2</sub>. For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. The simulated structures of N<sub>3</sub>, TiO<sub>2</sub>/N<sub>3</sub> and C-TiO<sub>2</sub>/N<sub>3</sub> are shown in Fig 4-2. The simulated conduction band, valence band and band gap of TiO<sub>2</sub> and C-TiO<sub>2</sub> are shown in Table 4-1 (a), while HOMOs, LUMOs and band gap of photosensitizer are shown in table in Table 4-1 (b). These tabulated values are in good agreement with the experimental values [23,24]. The computed results show that the doping of MWCNTs (one of the allotropic form of carbon) on TiO<sub>2</sub> significantly reduces the band gap of TiO<sub>2</sub> cluster. This is because the CNTs possess lower value of  $E_{CB}$  ( $\sim 0$  eV vs. NHE) than that of TiO<sub>2</sub> ( $-0.5$  eV vs. NHE) [13], the charge equilibrium between CNTs and TiO<sub>2</sub> would cause a shift of apparent Fermi level ( $EF$ ) to more positive potential i.e. downward shift as shown in Fig 4-3. Moreover, the thermodynamic driving force for charge transfer ( $\Delta G^{\text{inject}}$ ) is defined as the energy difference between the excited state of photosensitizer and the conduction band edge of metal oxide. The downward positive shift due to MWCNTs can generate significant driving force to facilitate the charge transfer from the excited dye to the conduction band of the photoanode. The simulated  $\Delta G^{\text{inject}}$  value for C-TiO<sub>2</sub>/N<sub>3</sub> is greater than TiO<sub>2</sub>/N<sub>3</sub>, as indicated in Table 4-1(b).

The UV-vis absorption spectra of N3 in methanol and anchored to TiO<sub>2</sub> and TiO<sub>2</sub>-MWCNTs are shown in Fig 4-4(a). The two broad visible bands at 547 and 419 nm in N3 are assigned to metal-to-ligand charge-transfer (MLCT) origin. The bands in the UV at 322 nm are assigned as intra ligand ( $\pi$ - $\pi^*$ ) charge-transfer transitions. However, the absorption shifts to lower energy values when anchored to TiO<sub>2</sub> and TiO<sub>2</sub>-MWCNTs. This is due to the fact that on the electrode the carboxylate groups bind to the TiO<sub>2</sub> surface in which Ti<sup>4+</sup> acts as proton. The interaction between the carboxylate group and the surface Ti<sup>4+</sup> ions may lead to increased delocalization of the  $\pi^*$  orbital. The energy of the  $\pi^*$  level is decreased by this delocalization, which explains the red shift for the absorption spectra. But the TiO<sub>2</sub>-MWCNTs based photoanode has a greater red shift value as compared to pure TiO<sub>2</sub>. This is because the CNTs may exhibit photosensitizing properties, thus extending photovoltaic properties into the visible spectrum [25]. *Similarly, the* simulated absorption spectra of N<sub>3</sub>, N<sub>3</sub>-TiO<sub>2</sub> and N<sub>3</sub>-TiO<sub>2</sub>-MWCNTs are shown in Fig 4-4b are in good agreement with the experimental spectra. Thus, the COSMO solvation model with SOAP function is appropriate for computing the absorption spectra of systems.

The *I*-*V* curves of the DSSCs based on hybrid photoanodes are shown in Fig 4-5. While the device parameters, i.e.  $J_{sc}$ ,  $V_{oc}$  and FF are shown in Table 4-2. The DSSC with the highest efficiency is achieved in the case of 0.03%MWCNTs-TiO<sub>2</sub> film and is characterized by photo conversion efficiency is as high as 0.85%, which presents about 30 % increase with respect to pure TiO<sub>2</sub> (0.65%). Insertion of MWCNTs in TiO<sub>2</sub> network significantly enhances the efficiency of DSSC. This is because the incorporation of MWCNTs increases the surface area of hybrid anode and thus more dye loading.

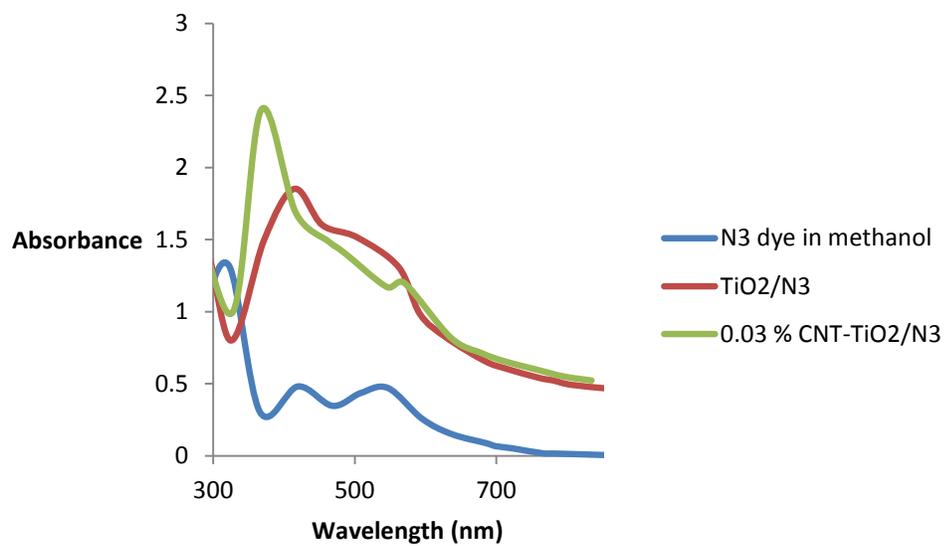

Fig 4-4(a). UV-Vis spectra of N<sub>3</sub>, TiO<sub>2</sub>/N<sub>3</sub> and CNTs-TiO<sub>2</sub>/N<sub>3</sub>

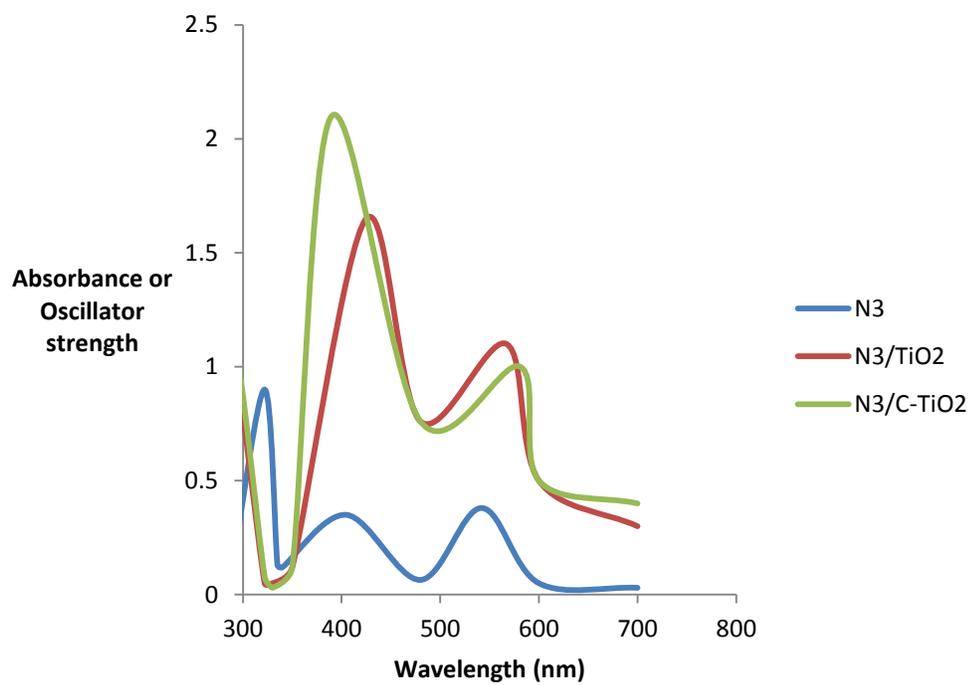

Fig 4-4(b). Simulated UV-Vis spectra of N<sub>3</sub>, TiO<sub>2</sub>/N<sub>3</sub> and CNTs-TiO<sub>2</sub>/N<sub>3</sub>

Moreover, the MWCNTs also improve the electron injection efficiency of the electrons due to increase positive potential (as described above). Simulation outcomes also favor these results. Table 4-1 (b) shows that absorptions (A) or oscillator strengths of N3, N3-TiO<sub>2</sub> and N3-TiO<sub>2</sub>-MWCNTs increase in the order of N3-TiO<sub>2</sub>-MWCNTs > N3-TiO<sub>2</sub> > N3. Thus, LHE will be in the order of N3-TiO<sub>2</sub>-MWCNTs > N3-TiO<sub>2</sub> > N3. It demonstrates that higher the LHE greater will be the photo current and hence more efficiency. However, the decline in Voc at increasing CNTs contents could be attributed to the downshift of the potential band edge of the TiO<sub>2</sub>. It can also be observed that increase in MWCNTs concentration from optimum level (0.03%) negatively affect the performance of DSSCs. This is because of the decrease in film transparency owing to increase MWCNTs contents. Another possibility of low efficiency at a high MWCNTs concentration could be attributed to the formation of CNT agglomerates inside the TiO<sub>2</sub> matrix acting as trapping sites that obstruct the fast charge collection at the electrodes. Such a poor charge collection at the electrode, together with enhanced light loss due to CNT direct absorption, strongly reduces the efficiency of DSSCs at high CNTs contents.

Electrochemical impedance spectroscopy (EIS) analysis is performed to further elucidate the photovoltaic properties. Figure 4-6(a) shows the Nyquist plots of DSSCs which were assembled with TiO<sub>2</sub>-N<sub>3</sub> and 0.03% MWCNTs-TiO<sub>2</sub>-N<sub>3</sub>. The large semicircle represents the interfacial charge transfer resistances (R<sub>3</sub>) at the photoanode/electrolyte interface. The R<sub>3</sub> is related to the charge recombination rate, e.g., a smaller R<sub>3</sub> indicates a faster charge recombination. The R<sub>3</sub> value for DSSC assembled with pure TiO<sub>2</sub> is smaller than that of 0.03% MWCNTs-TiO<sub>2</sub> DSSC as shown in Fig 4-6 (a), proposing charge recombination is greatly reduced owing to the incorporation of CNTs. However, the CNTs concentration

Table 4-3. The resistances and capacitance values of DSSC based on  $TiO_2$  and  $TiO_2$ -MWCNTs

Photo anode	$R_1(\Omega)$	$C_1$ (mF)	$R_2(\Omega)$	$C_2$ (mF)	$R_3(\Omega)$
$TiO_2$	20.62	20	6.235	0.57	37.15
$TiO_2$ -0.03%MWCNT	21	23	8.023	0.45	44.65

greater than 0.03 wt.% leads to the smaller values of  $R_3$  due to a shorter electron lifetime of the order of few tens of mili seconds [14]. Figure 4-6 (b) shows the equivalent circuit model of DSSCs. The equivalent circuit model can describe the junction impedance, and the EIS measurement system can compute the value of junction impedance. Table 3-3 shows all the values of the equivalent circuit model.

Regardless of the PCE gains a significant enhancement when 0.03 wt.% CNTs is dispersed into the  $\text{TiO}_2$  paste, the absolute value (0.84%) is exceptionally lower than the highest efficiency hitherto achieved ( $\sim 12\%$ ) [5]. The reason is that the photoanode film is too thick (22 $\mu\text{m}$ ). For an effective charge collection, the film thickness should be less than the electron diffusion length [26]. The reported diffusion length of electrons in  $\text{TiO}_2$  film is about 9–11  $\mu\text{m}$  based on electron transport studies [27–29]. A thick photoanode results in a long electron diffusion distance to the FTO substrate (electrode) which increases the probability of recombination and thus degrades the efficiencies [30].

#### **4.5. Conclusion**

In conclusion, we established that the dispersion of small of MWCNTs in  $\text{TiO}_2$  can significantly improve the photo conversion efficiency of DSSCs. Optimum concentration (0.03%) of CNTs does not affect the transparency of the  $\text{TiO}_2$  layer, while significantly increasing charge collection at the photoanode. The enhancement of electron lifetime, dye loading and the reduction of recombination phenomena lead to an increase in PCE of the DSSCs, with a maximum value of 0.84% (corresponding to the addition of 0.030 wt % MWCNTs). Here, our simulation outcomes using DFT/TD-DFT also support the

experimental result. Hence, we presented a fast, cheap, and an effective means to increase the PCE of DSSCs.

## Abstract

Co-sensitization of two or more dyes on hybrid TiO<sub>2</sub>- MWCNTs photoanode is an effective approach to enhance the performance of a dye-sensitized solar cell (DSSC). In this work, N719 sensitizer is co-sensitized with N3. The co-sensitized device showed enhanced V<sub>OC</sub> and J<sub>SC</sub> in comparison to single-dye sensitized devices. Upon optimization, the device made of the 0.1Mm N<sub>3</sub> + 0.4mM N719 yielded J<sub>SC</sub> = 12.5 mA cm<sup>-2</sup>, V<sub>oc</sub> = 0.73V, FF= 0.45 and  $\eta$  = 4.1 %. This performance is superior to that of either of the individual DSSCs sensitized with N<sub>3</sub> (3.69%) and N719 (3.51 %) under the same conditions of fabrication. The efficiency of DSSCs was further improved to 4.46% by the incorporation of MWCNTs in TiO<sub>2</sub>. The hybrid TiO<sub>2</sub>/MWCNTs photoanodes with different concentrations of CNTs (0.04, 0.08, 0.12, 0.16 wt. %) were prepared using mixing technique. The optimized molar ratio of N3/N719 was used for the sensitization of hybrid photonodes. Density functional theory (DFT) was used to compute the band gaps of TiO<sub>2</sub> and C-TiO<sub>2</sub> clusters .

**Keywords:** Hybrid, multi-walled carbon nanotubes, co-sensitization, density functional theory

## 5.1.Introduction

Energy is the driving force for development, economic growth, automation, and modernization. Energy usage and demand are increasing globally and researchers have taken this seriously to fulfill future energy demands<sup>1,2</sup>. At present global energy sources are mainly dependent on fossil fuels and the use of fossil fuel is the main reason for global increases of CO<sub>2</sub> amount<sup>3</sup>. According to global carbon emissions sources<sup>4</sup>, carbon dioxide emissions from coal, oil, natural gas, cement, and gas flaring were 43%, 33%, 18%, 5.3%, and 0.6%, respectively in 2012. Emissions of greenhouse gases grew 2.2% per year between 2000 and 2010, compared with 1.3% per year from 1970 to 2000<sup>5</sup>. The world is not capable of absorbing large amounts of CO<sub>2</sub> at the rate it is produced by fossil fuels. As a result, increasing the volume of CO<sub>2</sub> in the environment has increased global warming and further climate change. Global warming and climate changes are challenging all over the world. The use of renewable energy provides benefits that reduce emissions of air pollutants as well as greenhouse gases. Therefore, alternative sources of energy are needed so that mankind can survive on the Earth without depending on fossil fuels. Solar energy is one of the renewable energy sources that will contribute to the security of future energy supplies<sup>6,7</sup>. Solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times the current energy demands<sup>8</sup>. Light from the sun can be harvested by dye-sensitized solar cells (DSSCs). DSSCs have attracted considerable attention due to an ideal compromise between efficiency and cost-performance<sup>9-11</sup>. The major component of the DSSCs is a dye. Its function is to absorb incoming sunlight and produce excitons. It is chemically bonded to the porous surface of the semiconductor.

However, the traditional dyes generally used in DSSCs suffer from narrow absorption spectra and/or low absorption intensity and therefore low efficiency of DSSCs<sup>10</sup>. To achieve higher cell efficiency, a certain sensitizer is needed so as to absorb incident light as much as possible. Currently, there is no single organic sensitizer which provides strong absorption in a wide range of wavelengths (400-900 nm)<sup>12</sup>. Therefore, the co-sensitization strategy is applied to the organic dyes with complementary absorption spectra to obtain a broader and a more intense absorption band, thus increasing the performance of the DSSC<sup>13-15</sup>. Many co-sensitization systems have been proposed and demonstrated improved photovoltaic performance, such as ruthenium complex co-sensitized with an organic dye<sup>16-18</sup>, porphyrin<sup>19-21</sup> or phthalocyanine<sup>22-24</sup> co-sensitized with an organic dye, and organic dye co-sensitized with another organic dye<sup>25,26</sup>. Another major cause of low efficiency of DSSCs is the recombination of injected electrons with the electrolyte (dark current)<sup>27</sup>. The incorporation of CNTs in TiO<sub>2</sub> films may improve the electron transport in DSSCs<sup>28-30</sup>, owing to the creation of complex interpenetrating networks and favorable electrical conductivity<sup>31,32</sup>. It is supposed that one-dimensional carbon nanostructures allow the photocurrent to flow more efficiently in DSSCs by increasing orientation orders.

In this work both approaches (co-sensitization and hybrid anode) were used simultaneously to improve the efficiency of DSSCs. Here, we also employed DFT and TD-DFT to find the band gaps and UV-Vis spectra of systems. It is an effective tool as compared to other high level quantum approaches because the computed orbitals are suitable for the typical MO-theoretical analyses and interpretations<sup>33</sup>.

## **5.2. Computer simulations of TiO<sub>2</sub> and C-TiO<sub>2</sub>**

All the DFT/TD-DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01). BAND mode was used to simulate the anatase TiO<sub>2</sub> clusters. The tetragonal anatase crystal structure was selected with single layer (001) surface slab. Then, we created 4×1 super cell from this slab. All atoms were mapped within the unit cell. Then, TiO<sub>2</sub> and carbon doped TiO<sub>2</sub> models were simulated by considering generalized gradient approximation (GAD) at Becke parameter, Lee-Yang-Parr (BYLP) level and triple- $\zeta$  polarization basis function. In all the calculations, the relativistic effects were taken into account by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

## **5.3. Experimentation**

Seven different samples of N<sub>3</sub>, N719 and N3 + N719 i.e. 0.5mM N<sub>3</sub>, 0.4mM N<sub>3</sub> +0.1 mM N719, 0.3mM N<sub>3</sub> +0.2 mM N719, 0.25mM N<sub>3</sub> +0.25 mM N719, 0.2mM N<sub>3</sub> +0.3 mM N719, 0.1mM N<sub>3</sub> +0.4 mM N719 and 0.5mM N719 were prepared in methanol. DSSCs (TiO<sub>2</sub> based) were first fabricated (in open atmosphere) using these co-sensitization systems and then characterized to find the best system. The best co-sensitization system was then employed in hybrid TiO<sub>2</sub>-MWCNTs based DSSCs to further improve the efficiency/performance.

### **5.3.1. Preparation of composite anodes**

A suspension of ethanol and MWCNTs was prepared by dissolving 30 mg of MWCNTs (OD 10-20 $\mu$ m, purity > 95%, Ash <1.5%) in 25 ml ethanol. It was then sonicated for 4hr to attain a good dispersion of MWNTs in ethanol. An exact quantity of dispersed MWCNTs was mixed with known amount of anatase TiO<sub>2</sub> paste (T/SP **14451**, Solaronix)

to obtain a composite paste. Five different samples of TiO<sub>2</sub>-MWCNTs were prepared by varying the composition of MWCNTs i.e. 0, 0.04, 0.08, 0.12, 0.16wt. %. The TiO<sub>2</sub>-MWCNTs paste was then tape casted on FTO glass substrate (2 mm, 7Ω/seq, Solaronix). The coated glass substrate was annealed at 450°C for 30 min. Other photoanodes were prepared following the same procedure. The thickness of each photoanode was found by using cross sectional images obtained from SEM (JEOL, 6610LV). The average thickness of each film was 22 μm.

### **5.3.2. Fabrication of DSSCs**

TiO<sub>2</sub> and TiO<sub>2</sub>-MWCNTs electrodes were soaked in the dye solutions for 24 hours. After sensitization, the samples were washed with ethanol to eliminate unanchored dye. Then, DSSCs were fabricated employing the sensitized anode (TiO<sub>2</sub>, MWCNTs-TiO<sub>2</sub>), platinum deposited counter electrode (Plasticol T, Solaronix), 60 μm sealing spacer (Meltonix 1170, Solaronix) and I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple electrolyte prepared in methoxypropionitrile with a 50 mM redox concentration (Iodolyte Z-50, Solaronix). The active surface area of the solar cell was 0.35 cm<sup>2</sup>.

### **5.3.3. Characterization of DSSCs**

The UV-Vis spectra of dye solutions in methanol and adsorbed on TiO<sub>2</sub> and MWCNTs-TiO<sub>2</sub> films at glass substrates were recorded with JASCO-670 UV/VIS spectrophotometer. Keithley 2400 Source Meter was used to measure the *I-V* characteristics of the DSSCs using IV-5 solar simulator (Sr #83, PV Measurement, Inc) at AM1.5G (100 mWcm<sup>-2</sup>). The silicon solar cell was used as a reference for calibration. The impedance spectroscopy (EIS) was measured in dark conditions of illumination via

Bio-Logic SAS (VMP3, s/n:0373), with an AC signal of 10 mV in amplitude, in the frequency range between 10 Hz and 1MHz. The applied bias was between 0 and 750 mV above the  $V_{oc}$  of the DSSC.

## **5.4. Results and Discussion**

### **5.4.1. Morphological properties of composite anode**

The dispersion of MWCNTs in  $TiO_2$  was observed by TEM (JEOL, JEM-2100F) analysis.  $TiO_2$ -MWCNT sample having 0.16% CNT was selected for TEM analysis, because it was difficult to obtain TEM images of dispersed MWCNTs in  $TiO_2$  from low concentration samples. Fig 5-1 (b) shows that the CNTs are well dispersed in  $TiO_2$ , although a few tangles can be observed due to the length of the MWCNTs. The interface connection between MWCNTs and  $TiO_2$  can clearly be observed, indicating that  $TiO_2$  possesses good affinity with MWCNTs. The inner core is hardly visible, because the surface of MWCNT is well decorated with  $TiO_2$  nanoparticles as shown in Fig 5-1 (c).

### **5.4.2. Electrochemical properties**

The HOMOs, LUMOs and band gap energies of photosensitizers play an important role in providing the thermodynamic driving force for the electron injection to the conduction band of  $TiO_2$ . For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. The simulated structures of  $TiO_2$  and C- $TiO_2$  are shown in Fig 5-2. The simulated conduction band, valence band and band gap of  $TiO_2$  and C- $TiO_2$  are shown in Table 5-1. These tabulated values are in good agreement with the experimental values<sup>34</sup>. The computed results show that doping of MWCNTs (one of the allotropic form of carbon) on  $TiO_2$  significantly reduces the band gap of  $TiO_2$

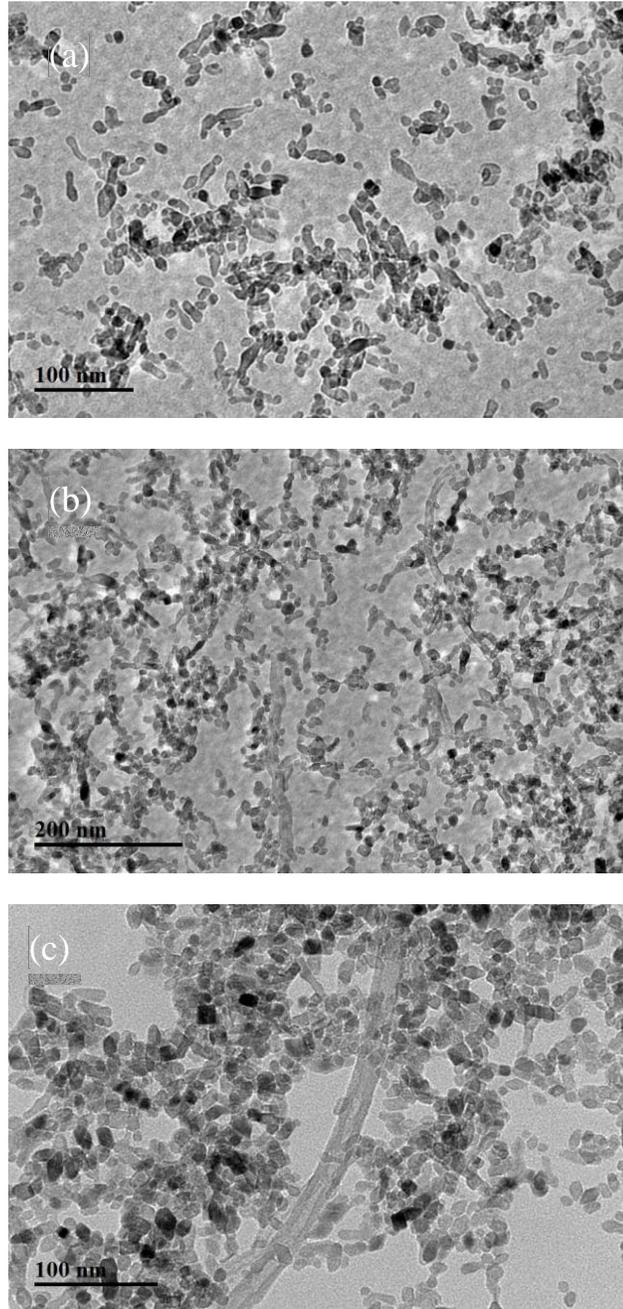

Fig 5-1: TEM images of a 0.16 % sample (a) Pure TiO<sub>2</sub> b) Dispersion of MWCNTs in TiO<sub>2</sub> and c) Dispersion of single MWCNT in TiO<sub>2</sub>

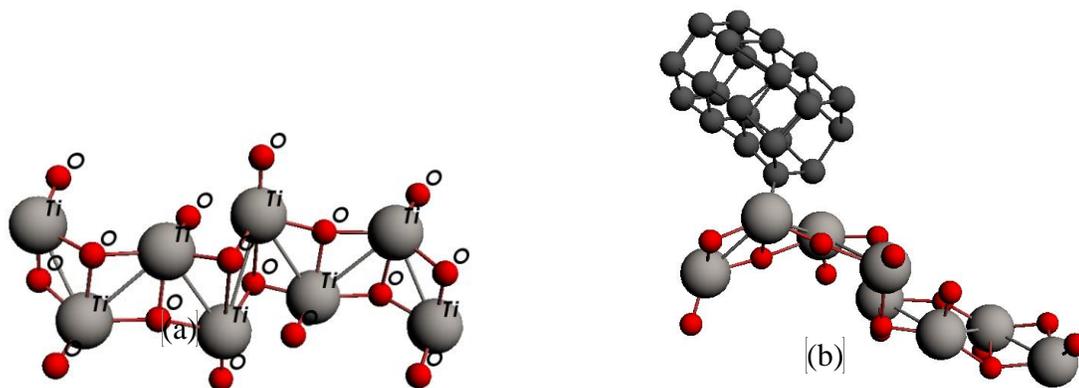

Fig 5-2: Simulated structures of TiO<sub>2</sub> (a) and CNT doped TiO<sub>2</sub>

Table 5-1: Simulated electronic structure properties of TiO<sub>2</sub> and carbon doped TiO<sub>2</sub>

System	$E_{CB}$ (eV)	$V_B$ (eV)	Band gap (eV)
TiO <sub>2</sub>	-7.2	- 4.10	3.1
C-TiO <sub>2</sub>	-7.2	-4. 30	2.9

cluster. This is because the CNTs possess the lower value of *the ECB* ( $\sim 0$  eV vs. NHE) than that of  $\text{TiO}_2$  ( $-0.5$  eV vs. NHE)<sup>29</sup>. The charge equilibrium between CNTs and  $\text{TiO}_2$  would cause a shift of apparent Fermi level to more positive potential i.e. downward potential. The downward positive shift due to MWCNTs (carbon, in the case of simulation) can cause a significant driving force to expedite the charge transport from the dye to the photoanode.

### 5.4.3. Optical properties

UV-Vis spectra of N719, N3 and N719+N3 are shown in Fig 5-4 (a). N3 and N719 share similar absorption spectra as well as molecular structures. The broad visible peaks at 528, 526 and 382, 384 nm in N719 and N3 respectively, are assigned to metal-to-ligand charge transfer (MLCT) origin. The bands in the UV at 314, 312 nm are assigned as intra ligand ( $\pi$ - $\pi^*$ ) charge-transfer transitions. High absorption is observed for overall wavelengths in the absorption spectrum of 0.1mM N3 + 0.4mM N719 due to the synergistic effect of the two dyes. But *less* pronounced enhancement in the absorption peak height indicates lower probability of hydrogen bond formation between the two dyes. However, the absorption spectrum of 0.1mM N3 + 0.4mM N719 shifts to lower energy values when anchored to  $\text{TiO}_2$ , shown in Fig 5-4 (b). It is due to the binding of the carboxylate groups (from both dyes) to the  $\text{TiO}_2$  surface in which  $\text{Ti}^{4+}$  acts as proton. The interaction between the carboxylate groups and the surface  $\text{Ti}^{4+}$  ions may lead to increased delocalization of the  $\pi^*$  orbital. The energy of the  $\pi^*$  level is decreased by this delocalization, which explains the red shift for the absorption spectrum. Moreover, the

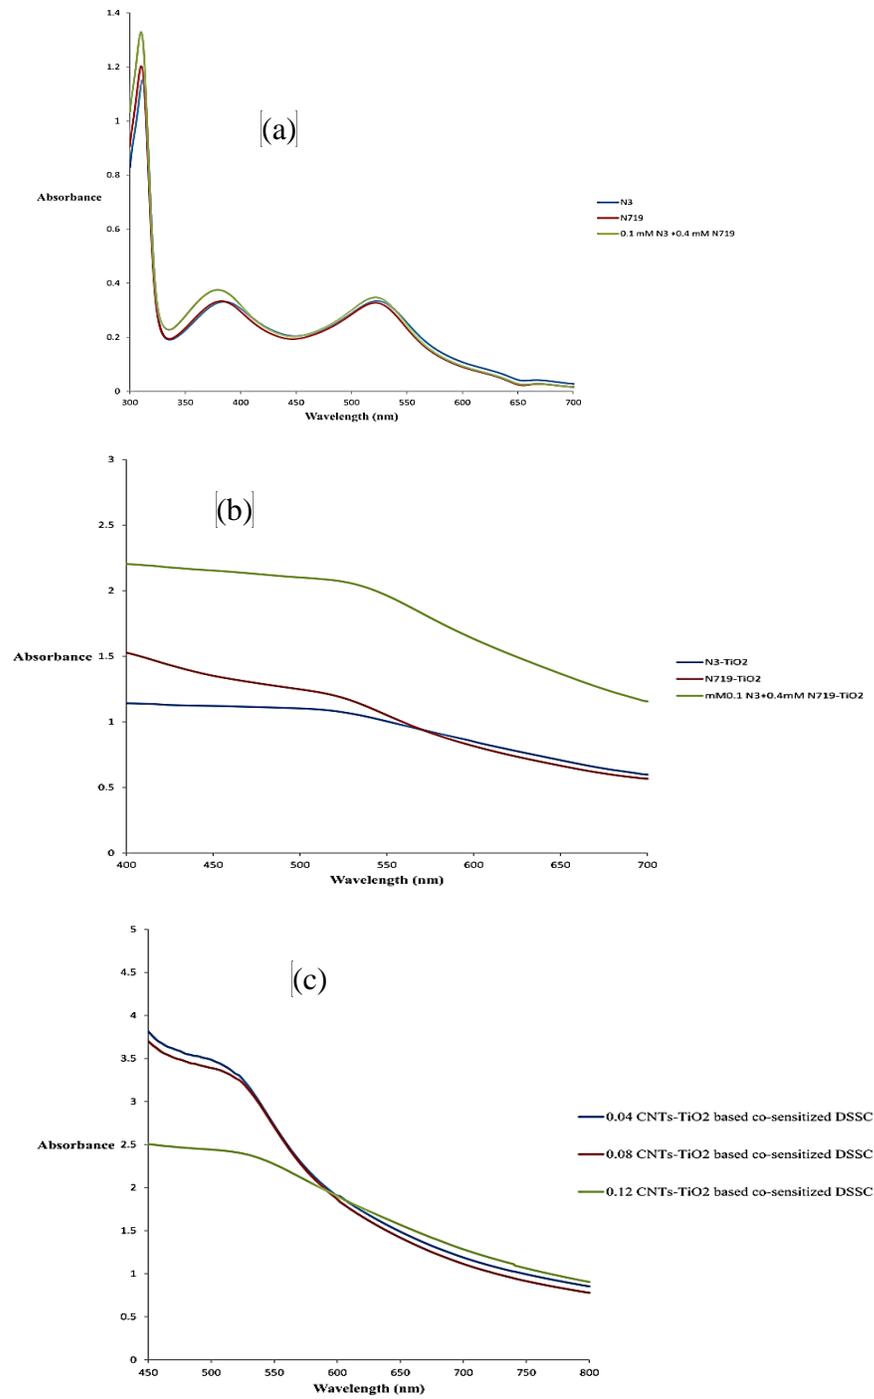

Fig 5-3 :(a) UV-Vis spectra of a) pure dyes in solvent b) Dyes anchored to TiO<sub>2</sub> film and c) dye anchored to MWCNTs-TiO<sub>2</sub> hybrid composite film.

absorption spectrum of TiO<sub>2</sub>/N<sub>3</sub>+N719 is more intense and broader as compared to individual dyes anchored to TiO<sub>2</sub>. It means that the proposed co-sensitized thin films can absorb more photons than the individual sensitized TiO<sub>2</sub> films. Similarly, the co-sensitized based MWCNTs-TiO<sub>2</sub> thin films show high absorption as compared to TiO<sub>2</sub> co-sensitized film, shown in Fig5-4(c). This is because the CNTs may exhibit photosensitizing properties, thus extending photovoltaic properties into the visible spectrum<sup>35</sup>. However, the further increase in CNTs contents from an optimum level (0.04%) decreases the absorption of co-sensitized films (0.08% and 0.12%) due to diminution in film transparency.

#### 5.4.4. Photovoltaic performance

Fig 5-4 (a) shows the current-voltage (*I-V*) characteristics of the TiO<sub>2</sub> based DSSCs, sensitized/co-sensitized by N719, N<sub>3</sub> and N<sub>3</sub>+N719. While Fig 5-4 (b) shows the (*I-V*) characteristics of the hybrid photoanode MWCNTs-TiO<sub>2</sub> based DSSCs, co-sensitized by 0.1mM N<sub>3</sub>+0.4mM N719. The photovoltaic parameters of DSSCs, i.e.  $J_{sc}$ ,  $V_{oc}$  and FF are shown in Table 2. Under a standard AM 1.5G simulated sunlight irradiation, the N719 sensitized DSSC gave a  $J_{sc}$  of 11.31 mA·cm<sup>-2</sup>, a  $V_{oc}$  of 739 mV, and a FF of 41.98%, resulted in an efficiency of 3.51%. Moreover, the N<sub>3</sub> sensitized DSSC yielded a  $J_{sc}$  of 12 mA·cm<sup>-2</sup>, a  $V_{oc}$  of 741 mV, a FF of 42%, and a efficiency of 3.7%. Encouragingly, compared with the devices sensitized by N<sub>3</sub> or N719 alone, the co-sensitized (N<sub>3</sub>+N719) DSSC exhibited a significantly improved efficiency of 4.10%. The improvement in the efficiency is mainly due to the enhancement of the  $J_{SC}$  values (14.2 mA·cm<sup>-2</sup>), which are highly related to the range and the intensity of the absorption spectrum. The overall efficiency of DSSCs was further improved to 4.46% by the

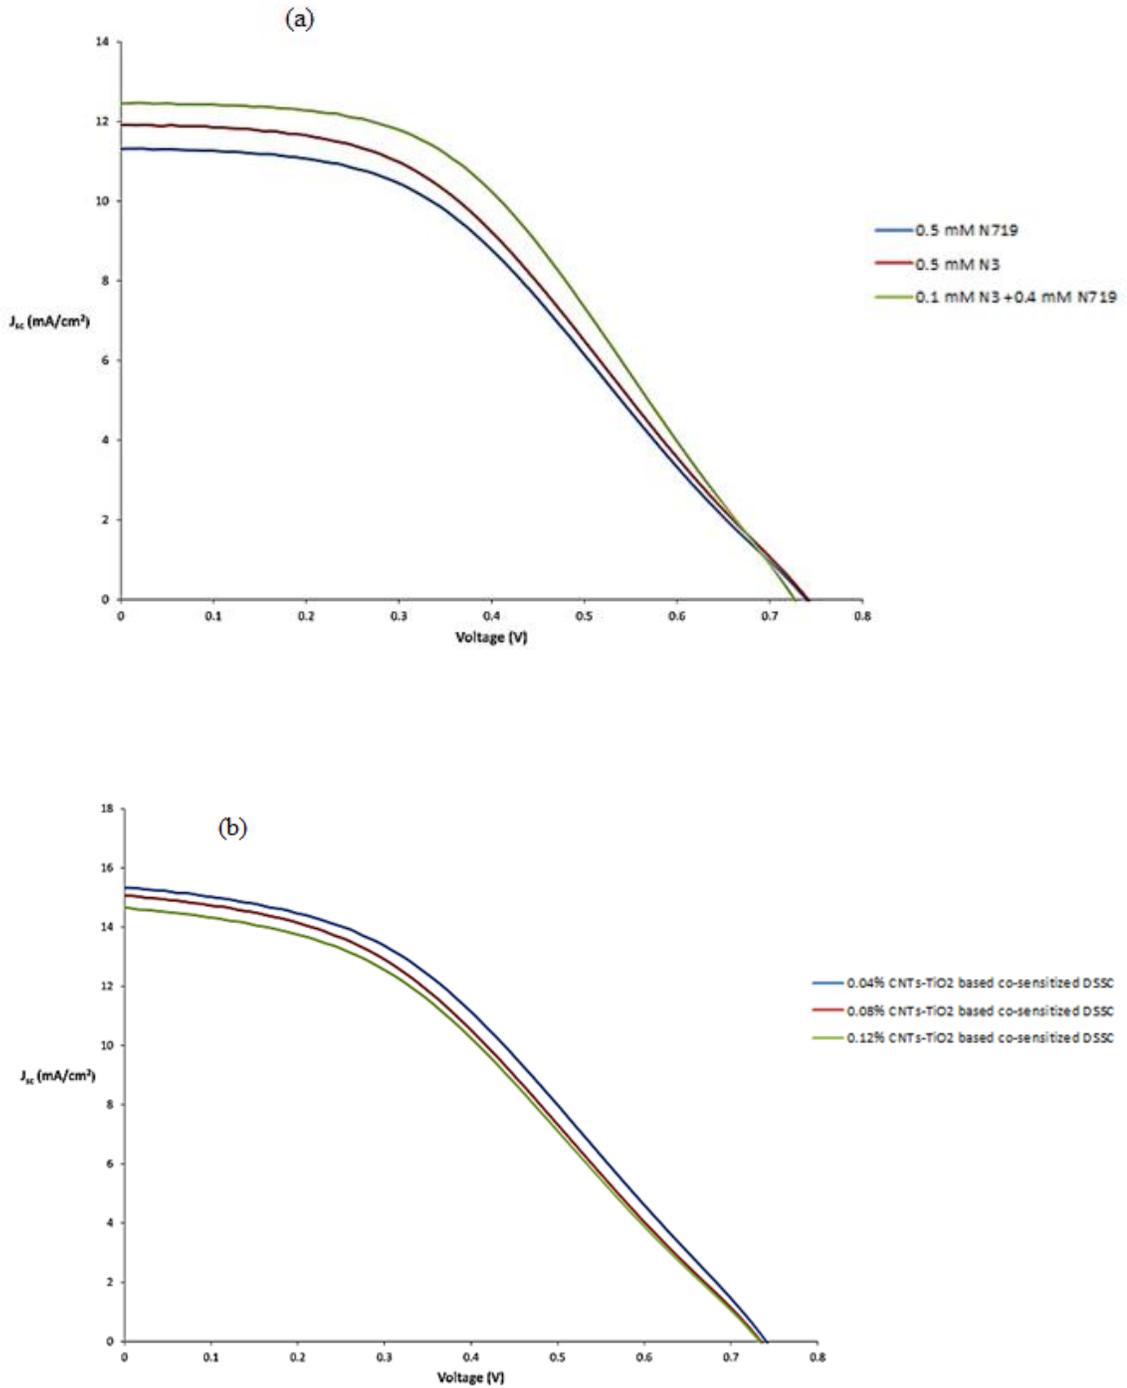

Fig 5-4: Current – voltage characteristics of DSSCs fabricated using a) TiO<sub>2</sub> and b) MWCNTs-TiO<sub>2</sub>.

Table 5-2 :Photovoltaic properties of DSSCs

<b>DSSCs</b>	<b><math>j_{sc}</math> (mA/cm<sup>2</sup>)</b>	<b><math>V_{oc}</math> (mV)</b>	<b>FF(%)</b>	<b><math>\eta</math> (%)</b>
TiO <sub>2</sub> /0.5mM N719	11.312	739	42.00	3.51
TiO <sub>2</sub> /0.5mM N <sub>3</sub>	11.970	741	41.77	3.69
TiO <sub>2</sub> /0.4mM N719+ 0.1mM N <sub>3</sub>	12.500	727	45.30	4.10
TiO <sub>2</sub> /0.3mM N719+ 0.2mM N <sub>3</sub>	13.700	742	39.70	4.00
TiO <sub>2</sub> /0.25mM N719+ 0.25mM N <sub>3</sub>	12.219	750	41.65	3.81
TiO <sub>2</sub> /0.2mM N719+ 0.3mM N <sub>3</sub>	12.731	760	40.50	3.90
TiO <sub>2</sub> /0.1mM N719+ 0.4mM N <sub>3</sub>	12.801	744	38.30	3.65
0.04%CNTS-TiO <sub>2</sub> /0.4mM N719+ 0.1mM N <sub>3</sub>	15.331	741	39.25	4.46
0.08%CNTS-TiO <sub>2</sub> /0.4mM N719+ 0.1mM N <sub>3</sub>	15.059	734	38.10	4.21
0.12%CNTS-TiO <sub>2</sub> /0.4mM N719+ 0.1mM N <sub>3</sub>	14.700	731	38.25	4.12

Incorporation of MWCNTs in TiO<sub>2</sub>. Insertion of MWCNTs in TiO<sub>2</sub> network significantly enhances the efficiency of DSSC. This is because the incorporation of MWCNTs : a) increases the surface area of hybrid anode and thus more dye loading, b) enhances light harvesting efficiency and thus more photo current and hence more efficiency and c) improve the electron injection efficiency of the electrons due to increase positive potential (as described above in sec 5-4.2). The little decline in V<sub>oc</sub> at increasing CNTs contents could be attributed to the downshift of the potential band edge of the TiO<sub>2</sub>. However an increase in MWCNTs concentration from an optimum level (0.04%) negatively affects the performance of DSSCs owing to decrease in film transparency. Another possibility of low efficiency at a high MWCNTs concentration could be attributed to the formation of CNT agglomerates inside the TiO<sub>2</sub> matrix acting as trapping sites that obstruct the fast charge collection at the electrodes. Therefore, the poor charge collection at the photoanode and light losses due to CNT direct absorption, diminish the efficiency of DSSCs at high CNTs contents.

#### **5.4.5. Electrochemical impedance spectroscopy (EIS) analysis**

EIS analysis is performed to further elucidate the photovoltaic properties. Fig 5-5 shows the Nyquist plot of DSSCs which were assembled with N719, N3, 0.1mM N3 + 0.4mM N719 and hybrid CNTs-TiO<sub>2</sub> co-sensitized. Generally, a normal impedance spectra of DSSCs is represented by three arcs (semicircles). The first semicircle represents the interface resistance of electrons at counter electrode/electrolyte ( $R_1$ ), second signifies the interface resistance at the photoanode / electrolyte ( $R_2$ ), and the third indicates the diffusion process of I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple in electrolyte ( $Z_w$ )<sup>36,37</sup>. Only second arc comes out in the Nyquist plot in the Fig 5-5. It is probable that the other two arcs corresponding

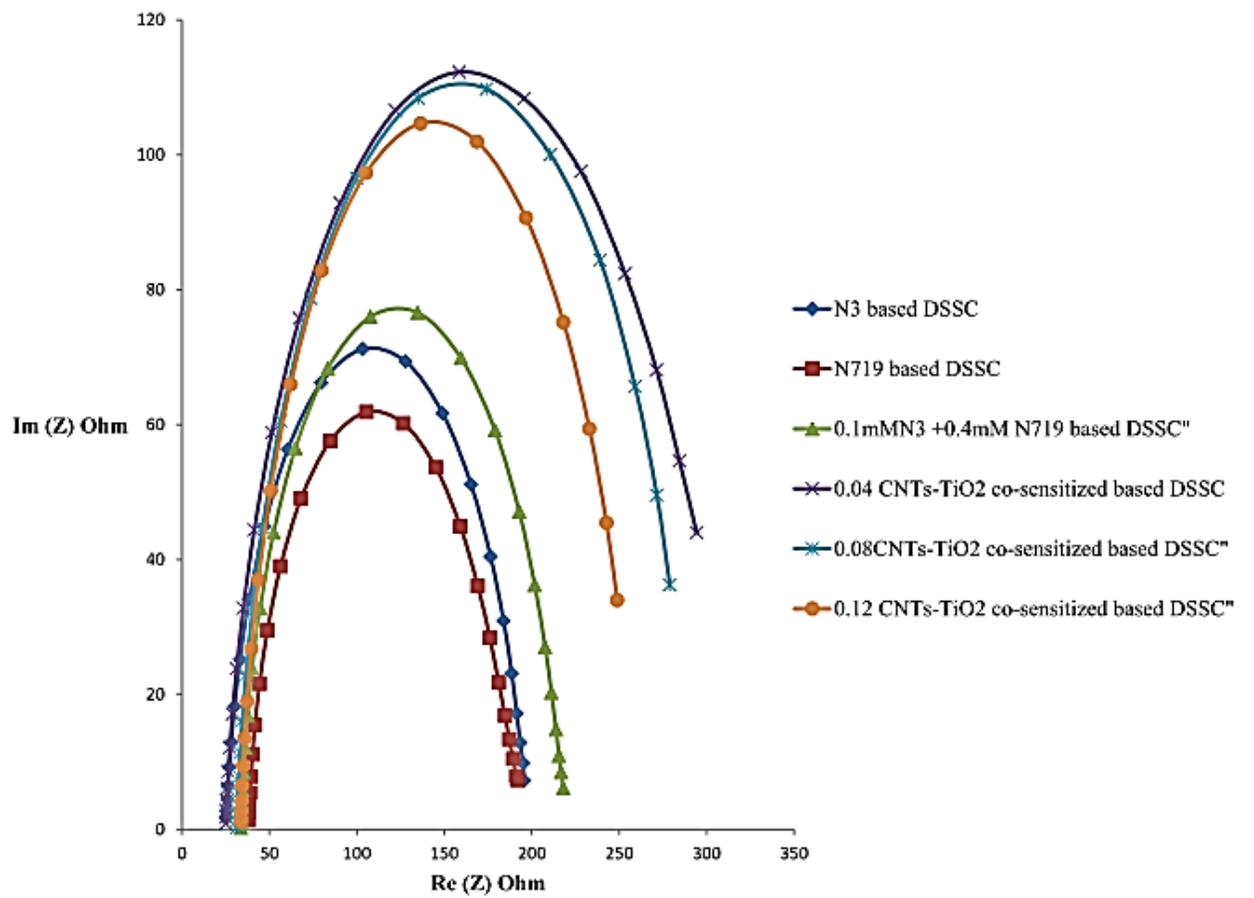

Fig 5-5 :EIS investigation of TiO<sub>2</sub> and TiO<sub>2</sub>-MWCNTs based DSSCs

to  $R_1$  and  $Z_w$  are overshadowed by large semicircle representing  $R_2$ <sup>38,39</sup>. The  $R_2$  is related to the charge recombination rate, e.g., a smaller  $R_2$  indicates a faster charge recombination. It can be clearly seen in Fig 5-5 that the radius of the semicircle for 0.1mM N3+0.4mM N719 based DSSC is greater than the based on the single dye and therefore possess high electron life time. The longer electron lifetime for DSSC based on cosensitization may be either due to a higher surface coverage of dye on the  $TiO_2$  surface after cosensitization that block the approach of  $I_3^-$  to the free  $TiO_2$  surface and decrease the recombination of injected electron with  $I_3^-$  ions, or due to the less aggregation of individual dyes in cosensitized conditions that improves the electron injections. Reduction in charge recombination and electron life time were further improved by the incorporation of MWCNTs in  $TiO_2$ . The  $R_2$  value for  $TiO_2/0.1Mm N_3 + 0.4mM N719$  is smaller than that of 0.04% MWCNTs- $TiO_2/0.1Mm N_3 + 0.4mM N719$  DSSC, proposing charge recombination is greatly reduced owing by incorporation of CNTs. However, the CNTs concentration greater than 0.04 wt.% will lead to the smaller values of  $R_3$  due to a shorter electron lifetime of electrons<sup>30</sup>.

## 5.5. Conclusion

The mixed solution of N719 and N3 in methanol was used for the co-sensitization of the photoanodes of DSSCs. The absorption spectrum of the co-sensitized  $TiO_2$  films becomes more intense and broader than the absorption spectra of the individual N719 and N<sub>3</sub> dyes. The results indicate that the power conversion efficiency of DSSC based on 0.4N719+0.1N<sub>3</sub> is 17% and 11% higher than based on the individual dyes N719 and N<sub>3</sub> respectively. Moreover, the cell efficiency of the DSSC with a molar ratio of N<sub>3</sub>/N719 = 0.1/0.4 was further improved to 4.46% by the incorporation of MWCNTs in  $TiO_2$ .

Optimum concentration (0.04%) of CNTs in photoanode does not affect the transparency of TiO<sub>2</sub> layer, while significantly increases the PCE of DSSC. Thus, we established a fast and highly effective technique to enhance the light conversion efficiency of DSSCs.

## **Abstract**

Composite photoanodes for dye sensitized solar cells (DSSCs) were prepared by simple addition of graphene (GR) micro-platelets to TiO<sub>2</sub> nanoparticulate paste. Transmission electron microscopy (TEM) was used to confirm the presence of graphene in composite films after heating at 450 C for 30 minutes. TiO<sub>2</sub>/graphene based DSSCs with different concentrations of graphene (0, 0.03, 0.06, 0.09, 0.15, 0.21 wt. %) were fabricated using N749 photosensitizer. The UV-Visible absorption spectroscopy, photocurrent–voltage (*I–V*) characteristic and electrochemical impedance spectroscopy (EIS) measurements were carried out to characterize the cells. The results indicate that graphene/TiO<sub>2</sub> photoanode improves the performance of solar cell. This is because the graphene/titania electrode accelerates electronic transportation and suppresses the charge recombination. Under an optimal conditions, solar cell based on graphene/TiO<sub>2</sub> shows power conversion efficiency (PCE) of 4.1 %, which is about 30% greater than the cell based on pristine TiO<sub>2</sub> electrode (3.16%). The objective of this study is to develop a fast, cheap, and an effective means to increase the photo conversion efficiency (PCE) of DSSCs.

**Keywords:** Nanocomposite photoanodes, dye sensitized solar cell, graphene, Titania, power conversion efficiency.

## 6.1.Introduction

The use of renewable energy provides benefits that reduce emissions of air pollutants as well as greenhouse gases. Therefore, alternative sources of energy are needed so that mankind can survive on the Earth without depending on fossil fuels. Solar energy is one of the renewable energy sources that will contribute to the security of future energy supplies [1,2] Solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times the current energy demands [3]. Light from the sun can be harvested by dye-sensitized solar cells (DSSCs).DSSCs have attracted considerable attention during the last decade due to an ideal compromise between efficiency and cost-performance [4–6]. DSSCs comprise of a sensitized semiconductor (Photoelectrode) and a catalytic electrode (counter electrode) with an electrolyte sandwiched between them.The major component of the DSSCs is a dye. Its function is to absorb incoming sunlight and produce excitons. It is chemically bonded to the porous surface of a metal oxide semiconductor. So far, polypyridyl ruthenium sensitizers based solar cells have attained up to 11% conversion efficiency [7–9] . But it is still low for commercial applications.

The major cause of low efficiency of DSSCs is the recombination of injected electrons (from the dye to the conduction band of the semiconductor) with the electrolyte (dark current) [10,11]. Photoanode of DSSCs plays an important role in the separation and transportation of electrons. Carbon-based materials CNTs) [12–14] and more recently graphene [15,16] have been proposed as an additive material for  $\text{TiO}_2$  photoanode to increase the electron mobility, owing to their outstanding electronic properties. But the enhancement of PCE due to CNTs is limited by poor contact between CNTs and  $\text{TiO}_2$  [17]. Two dimensional Graphene nano carbon material was also introduced to prepare

the hybrid film. It has an excellent mobility of charge carrier ( $200\,000\text{ cm}^2\text{ V}^{-1}\text{ s}^{-1}$ ) [18] and large specific surface area ( $2630\text{ m}^2/\text{g}$ ) [19]. Jihuai Wu et al [17] introduced graphene into  $\text{TiO}_2$  by one step hydrothermal reaction and reported a 17.7 % increase in PCE of DSSC. Tang et al [20] embedded graphene sheets in  $\text{TiO}_2$  paste via molecular grafting and showed 1.68% efficiency, which is five times higher than that without graphene (0.32%). Sun et al [21] fabricated graphene/ $\text{TiO}_2$  nanocomposites electrode through heterogeneous coagulation method and reported 4.28% efficiency, which is 59% greater than that without graphene. However the efficiency of these cells is still lower; and the fabrication method of graphene/ $\text{TiO}_2$  nanocomposite is relatively complex. Here, we presented a fast, cheap, and one-step process to prepare the graphene/ $\text{TiO}_2$  photoanode. It is expected that the incorporation of graphene in photoanode may enhance the PCE of DSSCs by reducing the charge recombination .

## **6.2. Computer simulations**

The objective of the simulation is just to see the effect of carbon based materials on the band gap of  $\text{TiO}_2$ . All the DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01). BAND mode was used to simulate the anatase  $\text{TiO}_2$  clusters. The tetragonal anatase crystal structure was selected with single layer (001) surface slab. Then, we created  $4\times 1$  super cell from this slab. All atoms were mapped within the unit cell. Graphene is an allotrope of carbon in the form of a two-dimensional sheet. It is impossible to dope the 2D graphene sheet on  $\text{TiO}_2$  cluster in the ADF environment. Therefore, we only doped the single carbon atom on  $\text{TiO}_2$  cluster to find/simulate a band gap of C- $\text{TiO}_2$ .  $\text{TiO}_2$  and carbon doped  $\text{TiO}_2$  models were simulated by considering hybrid Becke parameter, Lee-Yang-Parr (B1YLP) level and triple- $\zeta$

polarization basis function. In all the calculations, the relativistic effects were taken into account by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

### **6.3.Experimental**

#### **6.3.1. Preparation of composite anodes**

A suspension of ethanol and graphene was prepared by dissolving 15 mg of graphene in 20 ml ethanol. It was then sonicated for 5hr to attain a good dispersion of graphene in ethanol. An exact quantity of dispersed graphene was mixed with known amount of anatase TiO<sub>2</sub> paste (T/SP **14451**, Solaronix) to obtain a composite paste. Five different samples of TiO<sub>2</sub>-graphene were prepared by varying the composition of graphenes i.e. 0, 0.03, 0.06, 0.09, 0.12, 0.15 wt. %. The composite paste was then tape casted on FTO glass substrate (2 mm, 7Ω/seq, Solaronix). The coated glass substrate annealed at 450°C for 30 min. Other photoanodes were prepared following the same procedure. The thickness of each photoanode was found by using cross sectional images obtained from SEM (JEOL, 6610LV). The average thickness of each film was 20 μm.

#### **6.3.2. Fabrication of DSSCs**

A 0.5 mM solution of N749 was prepared in methanol. The composite electrodes were soaked in the dye solution for 24 hours. After sensitization, the samples were washed with ethanol to eliminate unanchored dye. Then, DSSCs were fabricated employing the sensitized hybrid anode, platinum deposited counter electrode (Plasticol T, Solaronix), 60 μm sealing spacer (Meltonix 1170, Solaronix) and I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple electrolyte prepared in methoxypropionitrile with a 50 mM redox concentration (Iodolyte Z-50, Solaronix).

### 6.3.3. Characterization of DSSCs

The visible spectra of N719 in methanol and adsorbed on TiO<sub>2</sub> films at glass substrates were recorded with JASCO-670 UV/VIS spectrophotometer. Keithley 2400 Source Meter was used to measure the  $I-V$  characteristics of the DSSCs using IV-5 solar simulator (Sr #83, PV Measurement, Inc) at AM1.5G (100 mWcm<sup>-2</sup>). The silicon solar cell was used as a reference for calibration. The impedance spectroscopy (EIS) was measured in dark conditions of illumination via Bio-Logic SAS (VMP3, s/n:0373), with an AC signal of 10 mV in amplitude, in the frequency range between 10 mHz and 1MHz.

## 6.4. Results and Discussion

### 6.4.1. Morphological properties of composite anode

The dispersion of graphene in TiO<sub>2</sub> was observed by TEM (JEOL, JEM-2100F) analysis. TiO<sub>2</sub>-graphene sample having 0.15% graphene was selected for TEM analysis, because it was difficult to obtain TEM images (of dispersed graphene in TiO<sub>2</sub>) from low concentration samples. Fig 6-1(a) shows the TEM image of titania. Fig 6-1 (b) clearly demonstrates the crystalline nature of the graphene sheet. HRTEM was used to measure the graphene layer spacing in its crystalline lattice. The lattice spacing in graphene prepared by our method is 0.348 nm. While, Fig 6-1(c) shows the nanocomposit of Graphen-TiO<sub>2</sub>. Fig 6-1(c) also shows that graphene nanosheets tend to congregate together to form multilayer agglomerates.

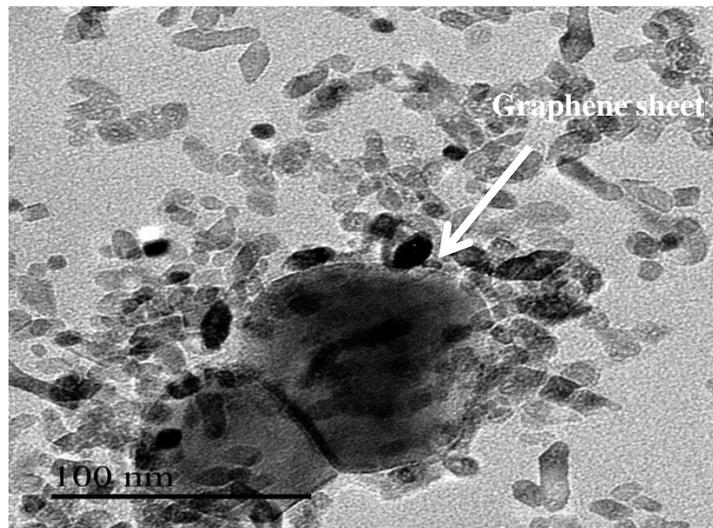

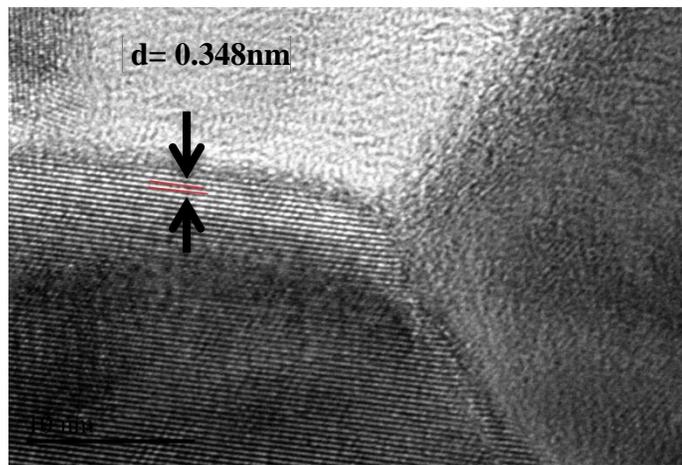

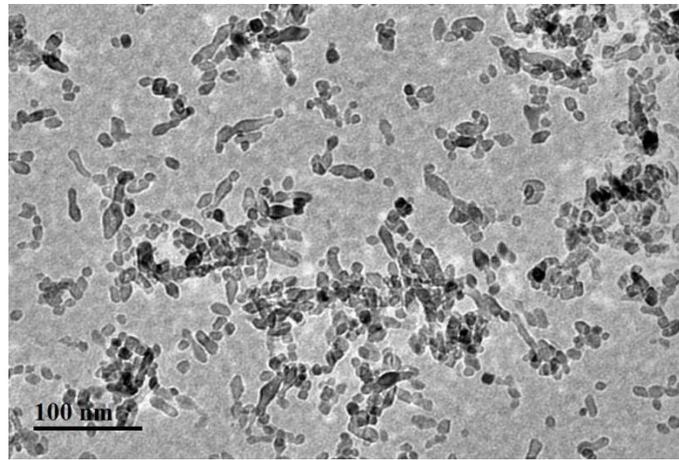

Fig 6-1: TEM images of a) TiO<sub>2</sub> nanoparticles b) lattice spacing in graphene and c) TiO<sub>2</sub>-Graphene nanocomposites

The dispersion of graphene in TiO<sub>2</sub> was observed by TEM (JEOL, JEM-2100F) analysis. TiO<sub>2</sub>-graphene sample having 0.15% graphene was selected for TEM analysis, because it was difficult to obtain TEM images (of dispersed graphene in TiO<sub>2</sub>) from low concentration samples. Fig -1(a) shows the TEM image of titania. Fig 6-1 (b) clearly demonstrates the crystalline nature of the graphene sheet. HRTEM was used to measure the graphene layer spacing in its crystalline lattice. The lattice spacing in graphene prepared by our method is 0.348 nm. While, Fig 6-1(c) shows the nanocomposit of Graphen-TiO<sub>2</sub>. Fig 6-1(c) also shows that graphene nanosheets tend to congregate together to form multilayer agglomerates.

#### **6.4.2. Effect of graphene on the band gap of TiO<sub>2</sub>**

The HOMOs, LUMOs and band gap energies of photosensitizers play a vital role in providing the driving force for the electron injection to conduction band of TiO<sub>2</sub>. For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. We used a DFT technique to find the band gap of TiO<sub>2</sub> and C-TiO<sub>2</sub>. The simulated structures of TiO<sub>2</sub> and C-TiO<sub>2</sub> are shown in Fig 6-2. While, the simulated conduction band, valence band and band gap of TiO<sub>2</sub> and C-TiO<sub>2</sub> are shown in Table-1. The computed results show that impregnation of graphene (one of the allotropic form of carbon) on TiO<sub>2</sub> significantly reduces the band gap of TiO<sub>2</sub> cluster. This is because the graphene possesses the lower value of *the*  $E_{CB}$  ( $\sim 0$  EV vs. NHE) [22] than that of the titania ( $-0.5$  eV vs. NHE) [23]. The charge equilibrium between graphene and TiO<sub>2</sub> would cause a shift of apparent Fermi level ( $E_F$ ) to more positive potential.

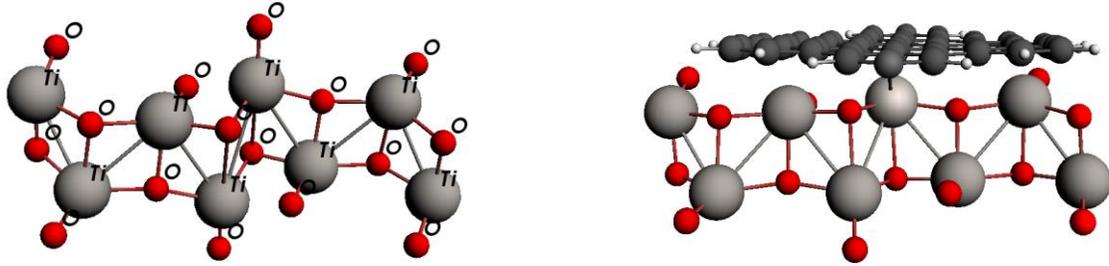

Fig 6-2. Simulated structures of a) TiO<sub>2</sub> and b) graphene doped TiO<sub>2</sub>

Table 6-1: Simulated electronic structure properties of TiO<sub>2</sub> and carbon doped TiO<sub>2</sub>

System	E <sub>CB</sub> (eV)	V <sub>B</sub> (eV)	Band gap (eV)
TiO <sub>2</sub>	-7.2	- 4.10	3.1
C-TiO <sub>2</sub>	-7.2	-4. 30	2.9

Moreover, the downward positive shift due to graphene can cause a significant driving force to expedite the electron transport from the sensitizer to the photoanode.

### 6.4.3. Photophysical properties

The visible spectra of N749 in methanol and anchored to TiO<sub>2</sub> and TiO<sub>2</sub>-graphene, are shown in Fig 6-4 (a) and 4 (b) respectively. The two broad visible bands at 608 and 415 nm in N749 are assigned to metal-to-ligand charge-transfer (MLCT) origin. The bands in the UV at 322 nm are assigned as intra ligand ( $\pi$ - $\pi^*$ ) charge-transfer transitions. However, the absorption shifts to lower energy values when anchored to TiO<sub>2</sub> and TiO<sub>2</sub>-graphene. This is due to the fact that on the electrode the carboxylate groups bind to the TiO<sub>2</sub> surface in which Ti<sup>4+</sup> acts as proton. The interaction between the carboxylate group and the surface Ti<sup>4+</sup> ions may lead to increased delocalization of the  $\pi^*$  orbital. The energy of the  $\pi^*$  level is decreased by this delocalization, which explains the red shift for the absorption spectra. But the TiO<sub>2</sub>-graphene based photoanode has a greater red shift value as compared to pure TiO<sub>2</sub>. This is because the graphene may exhibit photosensitizing properties, thus extending photovoltaic properties into the visible spectrum [24][25].

### 6.4.4. Photovoltaic properties of DSSCs based composite anode

Hybrid graphene/ TiO<sub>2</sub> based DSSCs were prepared with an effective area of 0.35 cm<sup>2</sup>. The photovoltaic parameters, short-circuit current density ( $J_{sc}$ ), open circuit voltage ( $V_{oc}$ ), fill factor (FF), and photovoltaic conversion efficiency ( $\eta$ ), are summarized in Table 2 and the corresponding  $I$ - $V$  curves are showed in Fig 4. The DSSC with the highest efficiency is achieved in the case of 0.09% MWCNTs-TiO<sub>2</sub>, which is about 30 % greater than the unmodified TiO<sub>2</sub> (3.16). This is because the incorporation of graphene increases the surface area of hybrid anode and thus more dye loading. However, the little decline in

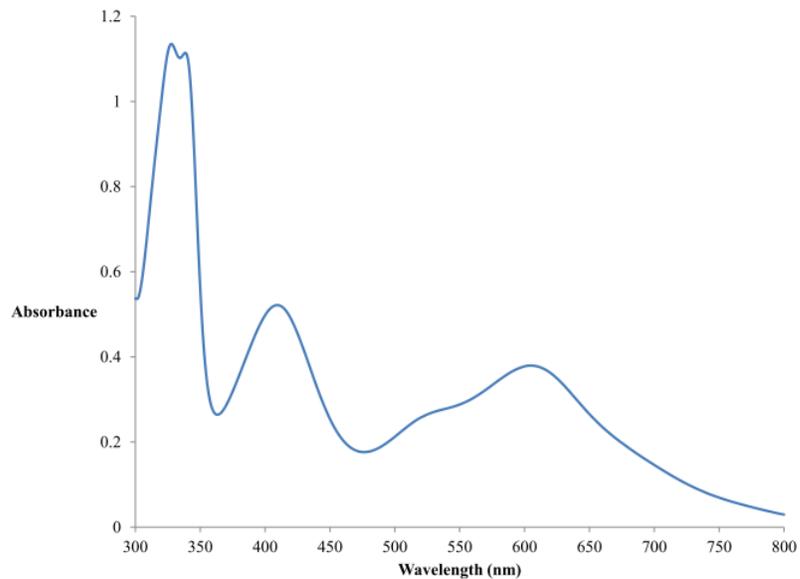

Fig 6-3 (a). UV-Vis spectra of N749 in methanol

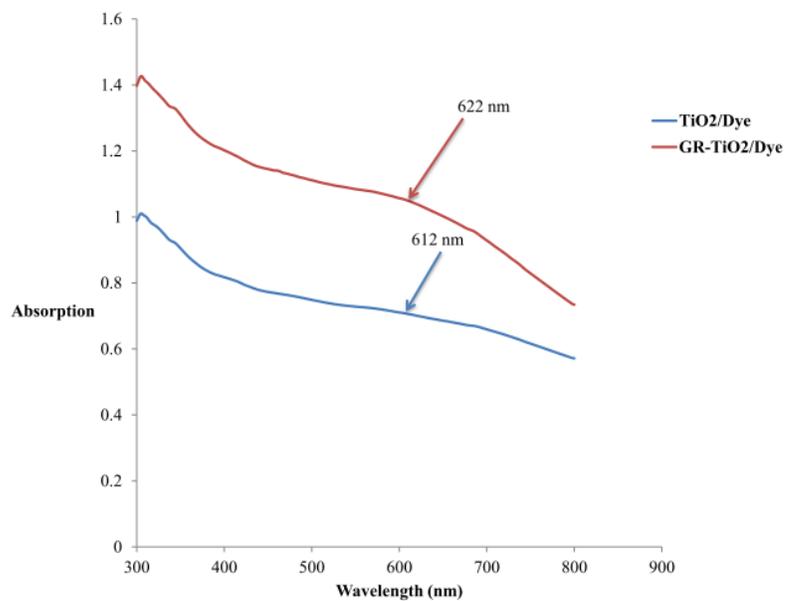

Fig 6-3 (b). UV-Vis spectra of TiO<sub>2</sub>/N749 and 0.09%GR+TiO<sub>2</sub>/N749

Voc at increasing graphene contents could be attributed to the downshift of the potential band edge of the TiO<sub>2</sub> conduction band. It can also be observed that increase in graphene concentration from optimum level (0.09%) negatively affects the performance of DSSCs. This is because of the decrease in film transparency owing to increase graphene contents. Another possibility of low efficiency at a high graphene concentration could be attributed to the formation of graphene agglomerates inside the TiO<sub>2</sub> matrix acting as trapping sites that obstruct the fast charge collection at the electrodes. The less charge collection together with light loss owing to graphene direct absorption, strongly declines the efficiency of DSSCs at high graphene contents.

Table 6-2 :Photovoltaic properties of DSSCs

DSSCs	$j_{sc}$ (mA/cm <sup>2</sup> )	V <sub>oc</sub> (mV)	FF(%)	$\eta$ (%)
Pure TiO <sub>2</sub>	10.310	703.994	43.50	3.16
0.03%GR+TiO <sub>2</sub>	12.089	705.088	42.31	3.61
0.06%GR+TiO <sub>2</sub>	14.181	706.786	38.84	3.89
0.09%GR+TiO <sub>2</sub>	13.037	705.022	43.90	4.03
0.12%GR+TiO <sub>2</sub>	12.195	696.490	40.02	3.40
0.15%GR+TiO <sub>2</sub>	9.185	690.836	47.52	3.02

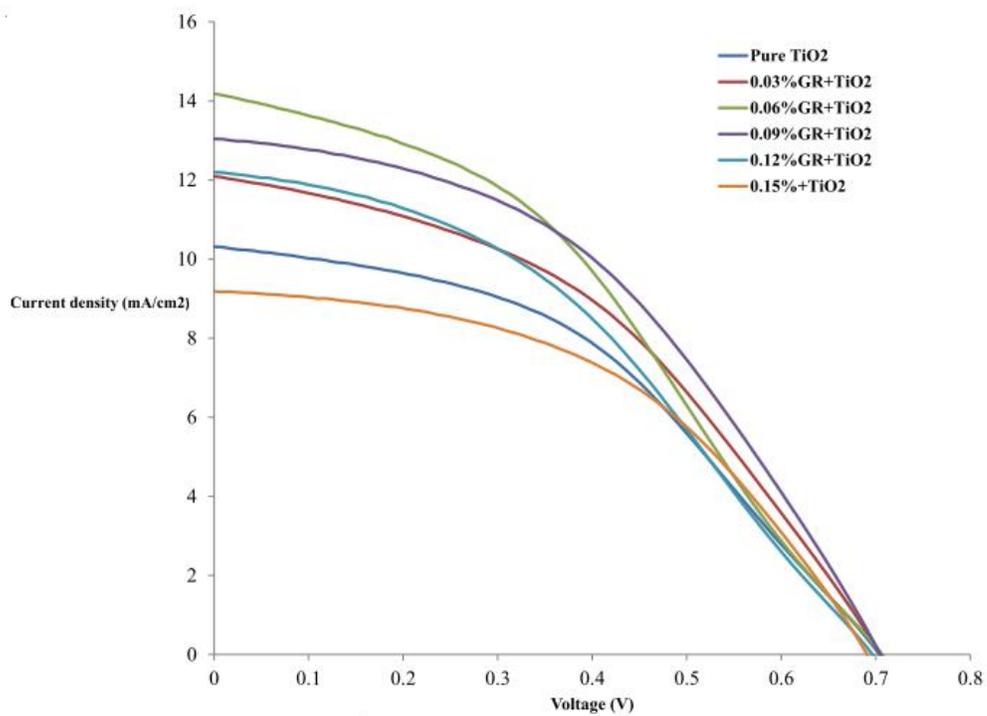

Fig 6-4: Current – voltage characteristics of DSSCs fabricated using different contents of graphene

#### 6.4.5. Electrochemical impedance spectroscopy

EIS analysis is performed to further explain the photovoltaic properties of DSSCs. Fig 6-5 shows the Nyquist plot of DSSCs which were assembled with  $\text{TiO}_2$ -N749 and graphene- $\text{TiO}_2$ -N749. Generally, a normal impedance spectrum of DSSCs is represented by three arcs (semicircles). The first semicircle represents the charge transport resistance at counter electrode/electrolyte ( $R_1$ ), second signifies the charge transport resistance at the photoanode / electrolyte interface ( $R_2$ ), and the third indicates the diffusion process of redox couple in electrolyte ( $Z_w$ ) [23,26]. Only second arc comes out in the Nyquist plot in the Fig 6-5. It is probable that the other two arcs corresponding to  $R_1$  and  $Z_w$  are overshadowed by larger semicircle reprinting  $R_2$  [27,28]. The  $R_2$  is related to the charge recombination rate, e.g., a high  $R_2$  value shows a lower charge recombination and vice versa. The  $R_2$  value for DSSC assembled with pure  $\text{TiO}_2$  is smaller than that of 0.09% graphene- $\text{TiO}_2$ , proposing charge recombination is greatly reduced owing to the incorporation of graphene. However, the graphene concentration greater than 0.09 wt.% will lead to the smaller values of  $R_2$  due to a shorter electron lifetime of the order of few tens of mili seconds [29].

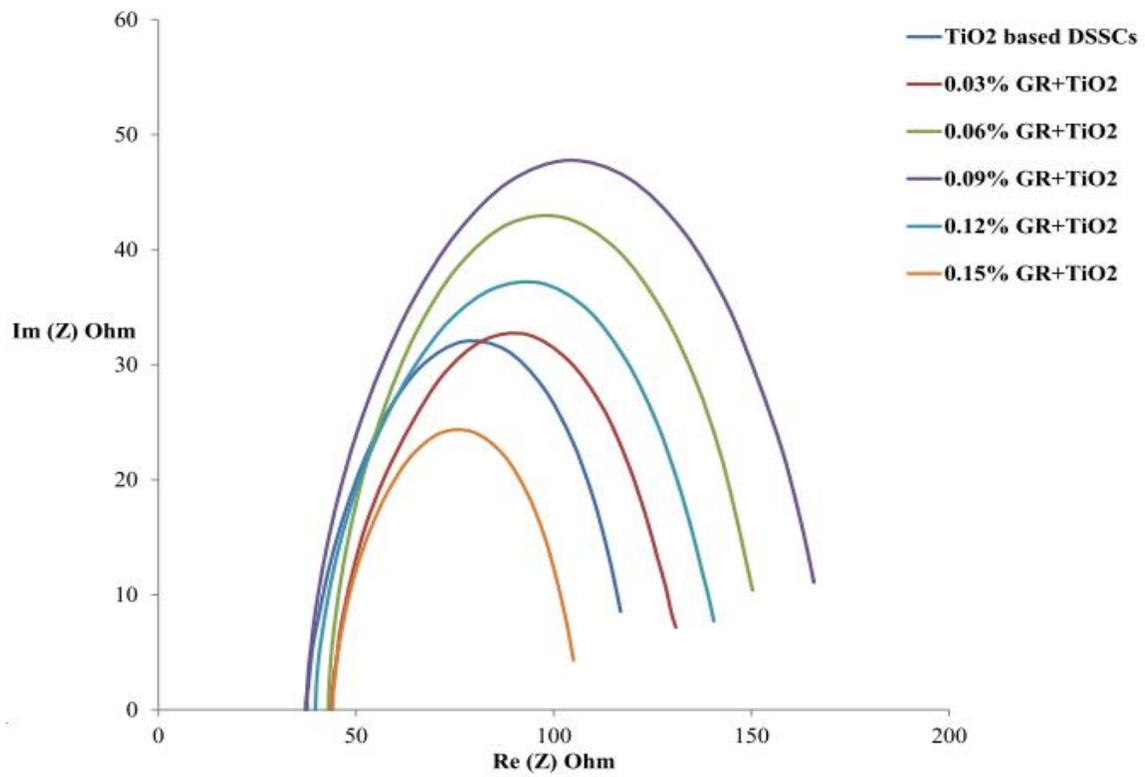

Fig 6-5. EIS investigation of TiO<sub>2</sub> and GR+TiO<sub>2</sub> based DSSCs

## **6.5. Conclusion**

We established a fast and highly reproducible methodology to fabricate DSSCs by simple addition of graphene sheets into a  $\text{TiO}_2$ . The incorporation of graphene in  $\text{TiO}_2$  slowing the recombination of photogenerated electrons, extending the excitation wavelength and increasing the surface-adsorbed amount of dye. We established that the dispersion of small amounts of graphenes in  $\text{TiO}_2$  can significantly improve the photo conversion efficiency of DSSCs. Optimum concentration (0.09%) of graphene in photoanode does not affect the transparency of  $\text{TiO}_2$  layer, while significantly increases the PCE of DSSC, with a maximum value of 4.12%. Thus, we established a profligate, economical, and highly effective technique to enhance the light conversion efficiency of DSSCs.

## **Abstract**

Complex organic compounds with benzene/thiophene as pi-segments are inspected as photosensitizers for applications in dye sensitized solar cells. To better understand the charge transport process involved in the dye sensitized solar cells, we used the results of Kohn–Sham density functional theory and time-dependent density functional theory (DFT) studies of benzene/thiophene based sensitizers as well as the dye bound to a TiO<sub>2</sub> nano cluster. We investigated the electronic structures and UV-Vis spectra of the sensitizers alone and linked to the cluster. We also showed energy level diagrams, the major transitions of molecular orbitals and free energy calculation of the electron transfer from the sensitizer to the conduction band of the TiO<sub>2</sub>. The results show that LUMO of the dyes is greater than the conduction band of TiO<sub>2</sub> indicating that a full charge transfer from dyes to the conduction band of TiO<sub>2</sub> is thermodynamically allowed. The calculated results also indicate that D3 is the most plausible sensitizer due to the most negative  $\Delta G_{\text{inject}}$  (0.91 eV) and a larger LHE value (0.95), which results in a higher IPCE.

**Keywords:** Density functional theory, benzene/thiophene, photosensitizers, free energy.

## 7.1.Introduction

The widespread commercialization of the photo voltaic (PV) cells is still limited mainly because of their high prices as compared to the amount of energy produced from them. Recent scientific research conducted for power conversion-efficiency reaches up to 24.2% [1], but is still non-competitive to the conventional electricity production sources. This relatively high cost is mainly due to the complex and expensive production process. Moreover, the need of highly purified silicon and use of toxic chemicals in their manufacturing, limits its use. These constraints encourage the scientists and researchers to divert their attention towards more efficient, economical and environment friendly solar cells. In this regard dye-sensitized solar cells (DSSCs) have received widespread attention in recent years because of their easy processing and low cost [2–5].

The major component of the DSSCs is a sensitizer. Its function is to adsorb an incoming sunlight and produce excitons. It is chemically bonded to the porous surface of the semiconductor. An efficient photosensitizer should: (i) possess intense absorption in the visible region (400 nm to 700 nm); (ii) adsorb strongly on the surface of the semiconductor; (iii) possess a high extinction coefficient; (iv) stable in its oxidized form, thus allows its reduction by an electrolyte; (v) stable enough to carry out  $\sim 10^8$  turnovers, which typically correspond to 20 years of cell operation [6]. Photosensitizers are categorized into the metal complex and metal-free organic sensitizers. But metal free organic photosensitizers are preferred over ruthenium based sensitizers because of their low cost and good transport properties. The basic structural unit of metal-free dyes are donor-pi-spacer-acceptor (D- $\pi$ -A). The photovoltaic properties of such dyes can be finely tuned by selecting suitable groups within the D- $\pi$ -A structure [7] . This D- $\pi$ -A dipolar

configuration creates an effective intramolecular charge transfer from donor to acceptor during electron excitation. Instead of this charge transfer from donor to acceptor, the performance of DSSCs significantly depends on the conjugated bridging system [8]. Organic dyes based on thiophene, oligothiophene moiety [9], 3,4-ethylenedioxythiophene (EDOT) [10], thieno (3,2-b) thiophene (TT) [11] and dithieno (3,2-b:2',3'-d) thiophene (DTT) [12] have been reported as efficient pi-bridging moieties, exhibits high values of the solar conversion efficiency. Thiophene, has been appeared as an attractive pi-bridging segment for the development of PV materials due to its rigid conjugation structure and facile introduction of alkyl chains. Thiophene based photosensitizers are expected to improve the overall efficiency of DSSCs [13,14].

In this research work, DFT is used to calculate the structural and optical properties of three dyes. Eventually, we compared the theoretical results with the experimental data available [14]. Kohn–Sham DFT/TD-DFT is an effective tool to investigate the ground and excited state properties of photosensitizer complexes compared to other high level quantum approaches, since the computed orbitals are appropriate for typical molecular orbital-theoretical studies and elucidations. Many theoreticians have successfully applied this approach [15–20].

## **7.2.Theoretical Background**

### **7.2.1. The Kohn–Sham molecular orbital (MO) model**

The fundamental assumption in Kohn–Sham density functional theory (KS-DFT) is that we can use a single electron calculation to “n” interacting electrons. It can be done by applying appropriate local potential  $V_{XC}(r)$ , external potentials  $V_{ext}(r)$  and the Coulomb potential of the electron cloud  $V_C(r)$ , then using Eq. (1)

$$\left(-\frac{1}{2}\nabla^2 + V_{\text{ext}}(r) + V_{\text{C}}(r) + V_{\text{XC}}(r)\right)\varphi_i(r) = \varepsilon_i\phi_i(r) \quad (1)$$

The potential  $V_{\text{XC}}$  is the functional derivative with respect to the density ( $\rho$ ) of the exchange-and-correlation energy functional  $E_{\text{XC}}[\rho]$ . The one-electron molecular orbitals (MOs)  $\phi_i$  with corresponding orbital energies  $\varepsilon_i$  define the exact electronic charge density and give access to all properties. The (first) derivatives of the energy with respect to nuclear displacements at the end of the self consistent field (SCF) method are used to find stationary points in the energy surface, particularly for the geometry optimization of molecules [21].

According to Runge-Gross theorem [22], the external potential individually finds out the density for a given interaction potential. While according to Kohn-Sham assumption the density of the non-interacting system is equal to the density of an interacting system. The benefit of this assumption is that, the wave function of a non-interacting system can be represented as a Slater determinant of single-particle orbitals, each of which are determined by a single partial differential equation in three variable. Then, the time-dependent (TD) Kohn-Sham equations are:

$$i\frac{\partial}{\partial t}\varphi_i(r, t) = \left(-\frac{\nabla^2}{2} + V[\rho](r, t)\right)\varphi_i(r, t) \quad (2)$$

$$\rho(r, t) = \sum n_j |\varphi_j(r, t)|^2 \quad (3)$$

The potential ( $V$ ) includes the  $V_C(r)$ , the nuclear potential,  $V_{ext}(r)$  and  $(X_C)$ , all are functions of time. KS-TDDFT technique with solvent effect is used to calculate the excitation energies ( $E_{ex}$ ) in DFT.

### 7.2.2. Computational Detail

In this work, all the DFT/TD-DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01). The ground state geometries of dyes and dye/(TiO<sub>2</sub>)<sub>8</sub> were optimized by applying a hybrid B3LYP level together with triple- $\zeta$  polarization basis function. (TiO<sub>2</sub>)<sub>8</sub> nanoparticles anatase cluster was also simulated by considering a generalized gradient approximation (GAD) at BYLP level and triple- $\zeta$  polarization basis function. UV-Vis spectra of these dyes were simulated in chloromethane solvent. Here the conductor-like screening model (COSMO) was selected to consider the effect of solvent. While the  $E_{ex}$  were examined using the TD-DFT and statistical average of orbital potentials (SAOP) model including the solvation effects. Eighty singlet-singlet transitions were selected to define the whole absorption spectrum. In all the calculations, the relativistic effects were also considered by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

We employed GGA-BLYP, GGA-PW91, GGA-PB-86-D and hybrid-B1LYP with triple- $\zeta$  (zeta) polarization basis function to optimize the dye structures. But the calculated results with hybrid-B1LYP (along with triple- $\zeta$ ) are in good agreement with the experimental data [14].

### 7.2.3. Parameter estimation equations

The performance of DSSCs is evaluated by an incident photon to conversion efficiency (IPCE). It is associated with charge collection efficiency ( $\eta_c$ ), electron injection efficiency ( $\Phi_{inj}$ ) and light harvesting efficiency (LHE) as [15],

$$IPCE = LHE \times \Phi_{inj} \times \eta_c \quad (5)$$

LHE can be calculated in the following way [23]

$$LHE = 1 - 10^f \quad (6)$$

Where “ $f$ ” is the absorption of dye associated with maximum absorption also called oscillator strength and  $\Phi_{inj}$  is related to the free energy of electron injection as [15]

$$\Phi_{inj} \propto f(-\Delta G_{inject}) \quad (7)$$

Eq-3 shows that the more negative  $\Delta G_{inject}$  the greater will be electron injection efficiency. While  $\Delta G_{inject}$  is the difference between the excited state oxidation potential ( $E_{ox}^{dye*}$ ) and the ground state reduction potential of the semiconductor conduction band ( $E_{CB}$ ) [19],

$$\Delta G_{inject} = E_{ox}^{dye*} - E_{CB} \quad (8)$$

TiO<sub>2</sub> cluster was also simulated and its  $E_{CB}$  was found to be -4.01 eV. Similarly,  $E_{ox}^{dye*}$  can be calculated by using the following equation [19],

$$E_{ox}^{dye*} = E_{ox}^{dye} - \Delta E \quad (9)$$

Where  $E_{ox}^{dye}$  (-HOMO) [17] is the dye's ground state oxidation potential and  $\Delta E$  is the lowest absorption energy associated with  $\lambda_{max}$ .

### 7.3. Results and discussion

#### 7.3.1. *Designed systems*

The structures and names of a new class of dyes are shown in Fig 7-1. In these structures, a 3,6-diiodocarbazole unit was used as the electron-donating moiety and carboxyl and cyano functional groups were inserted as the acceptor moiety and the anchor group owing to their good electron-extracting capability and strong adhesion to metal oxide. Benzene/thiophene or oligothiophene moiety was used as the  $\pi$ -conjugation spacers, which bridges the donor-acceptor systems. Benzene/thiophene as pi-bridge reduces the tendency to aggregate, but resistance to charge transfer between donor and acceptor increases. However, the insertion of thiophene moiety as a pi-bridge causes the red shift in absorption spectra. A double bond was also introduced to the pi-conjugation system to fine tune the planar molecular configuration and to broaden the absorption spectra.

#### 7.3.2. *Energy Levels*

The HOMOs, LUMOs, and the band gap energies of the photosensitizers play an important role in providing the thermodynamic driving force for the electron injection. For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. The electron distribution of the HOMOs and LUMOs of D1, D2 and D3 are shown in Fig 7-2. Clearly, the HOMOs of these compounds are the highest electron density located at the nitrogen atoms of the carbazole. The LUMOs are located in the anchoring group through the pi-bridge. Thus, the HOMO-LUMO excitation induced by light irradiation could move the electron distribution from the carbazole segment to the anchoring unit through the pi-bridge segment. **Table 7-1 shows that the**

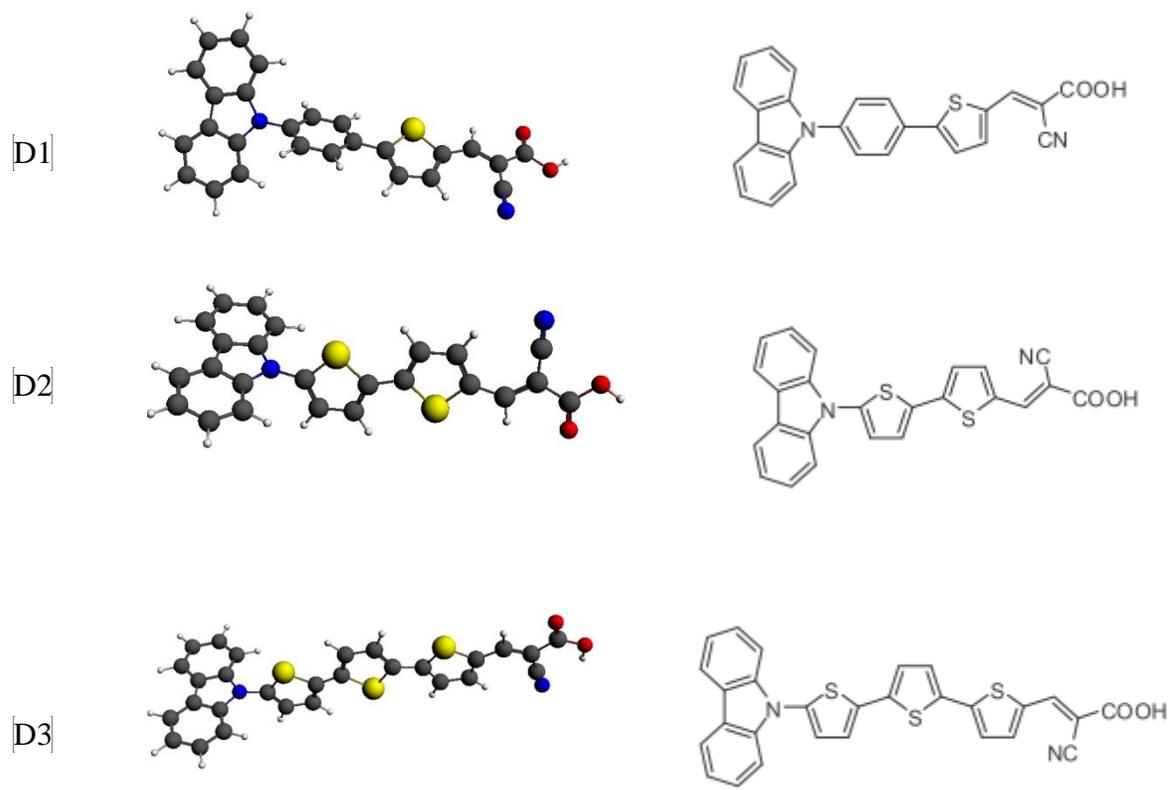

Fig 7-1:Chemical structures of organic dyes

HOMO levels of the dyes are in the order of D3 (-5.72) > D1 (-5.74) > D2 (-5.81). While, LUMO energy levels are in the order of D1 (-2.97) > D2 (-3.07) > D3 (-3.18). The insertion of thiophene unit as the  $\pi$ -conjugation unit significantly affects the HOMO and LUMO energy levels of the dyes. Similarly, the H-L<sub>gap</sub> of the dyes are in the order of D3 (2.54) < D2 (2.74) < D1 (2.77). These results suggest that dyes 1-3 can inject electrons to the conduction band of titanium oxide.

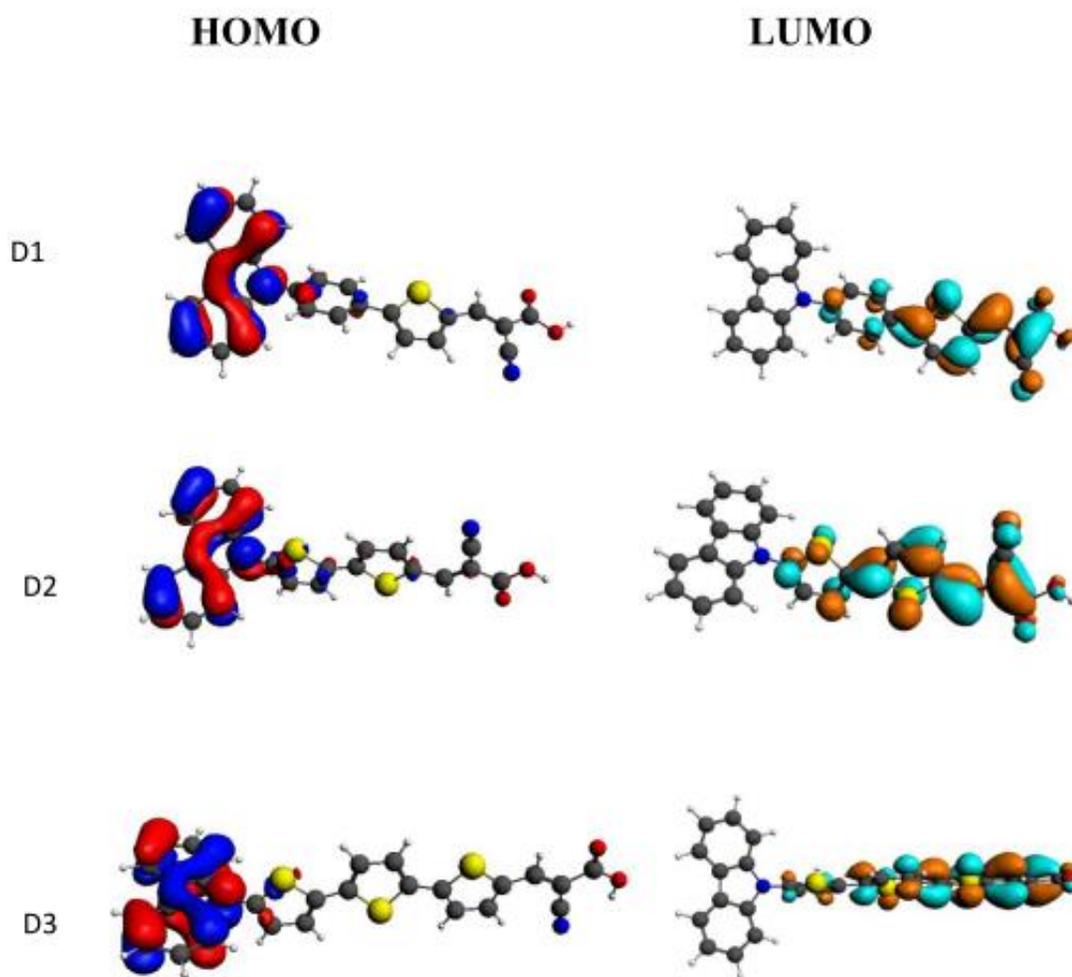

Fig 7-2 : Simulated HOMOs and LUMOs of dyes

**Table 7-1:** Simulated HOMOs (eV), LUMOs (eV) and H-L<sub>gap</sub> (eV) energies of dyes

Dyes	HOMO	LUMO	H-L <sub>gap</sub>
D1	-5.74	-2.97	2.77
D2	-5.81	-3.07	2.74
D3	-5.72	-3.18	2.54

### 7.3.3. UV-Vis absorption spectra of dyes

An efficient photosensitizer should show a strong absorption in the visible region (400 nm to 700 nm). TDDFT calculations have been performed on D1, D2 and D3 to find out the optical properties. These calculated results of dyes (D, D2 and D3) are in good agreement with the experimental data [14], which shows that SAOP function with the COSMO model is accurate in finding the absorption spectra of dyes. The simulated spectra of systems 1-3 are shown in Fig 7-3. All the absorption spectra of dyes can be clearly divided into two sections, with the first peak occurring in the 300-400 nm region and second in the 400-700 nm region. The band in the UV- region is probably emerging from the transitions of electrons localized within the carbazole unit. The absorption occurring in the visible region is due to transfer of electrons from donor to acceptor, which is sensitive to the nature of the conjugation pathway and red-shifts on progressive addition of thiophene units. The dye D2 with terthiophene as pi-bridge exhibits a significant red-shift as compared to D1 and D3. Also, the shorter peak position of the charge transfer transition for D1 (340 nm) is observed when compared with D2 (375 nm)

Table 7-2 :Optical, redox and energy level of photosensitizers

Dye	<sup>a</sup> $\lambda_{\max}$	<sup>b</sup> $\lambda_{\max}$ (Sim)	$\Delta E$ (eV)	$E_{\text{ox}}^{\text{dye}}$ (eV)	$E_{\text{ox}}^{\text{dye}*}$ (eV)	<sup>c</sup> $f$

**Table 7-3:** Free energy of electron injection  $\Delta G^{\text{inject}}$  (eV) and Light harvesting efficiency LHE

System	$\Delta G^{\text{inject}}$ (eV)	* LHE	Major Transitions
D1	-0.90	0.93	H-2 $\longrightarrow$ L (96%)
D2	-0.80	0.81	H-4 $\longrightarrow$ L (83%)
D3	-0.91	0.95	H $\longrightarrow$ L (98%)

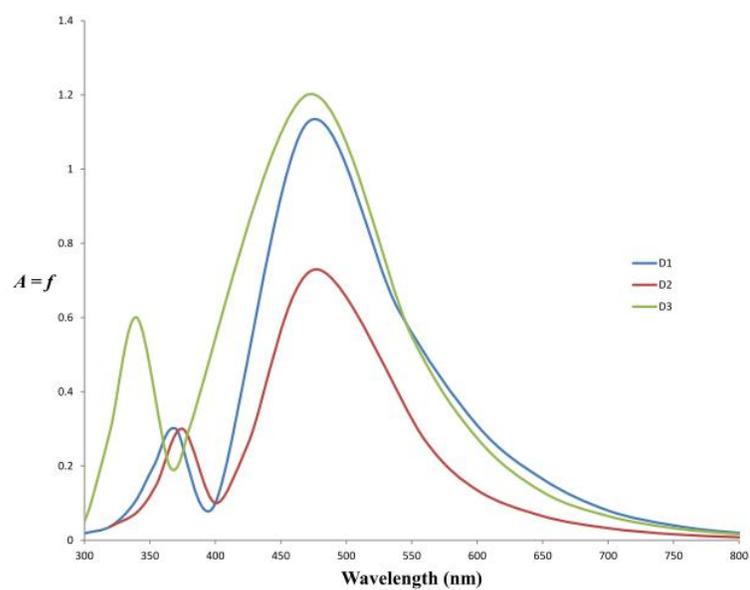

Fig 7-3: Simulated absorption spectra of systems 1-3

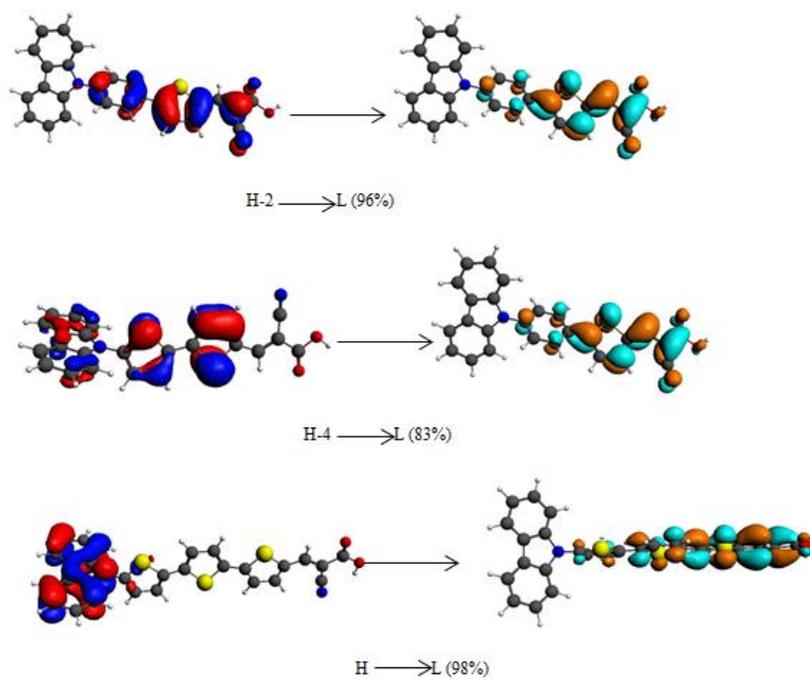

Fig 7-4: Major Transitions of system 1-3

and D3 (380), probably due to the deficiency of electrons in benzene relative to the thiophene unit.

Ground and excited state potential ( $E_{ox}^{dye}$ ), the maximum absorption ( $\lambda_{max}$ ), oscillation strength ( $f$ ), and the main transitions are presented in the Table 7-2. The main molecular orbitals (MOs) involved in the dominant electron transitions of systems 1-3 are shown in Fig 7-4. The major transitions may be attributed to the transfer of charge from the carbazole group to -COOH and -CN through the benzene/thiophene unit.

#### 7.3.4. Free energy of electron injection and light harvesting efficiency

LHE and  $\Delta G_{inject}$  can be calculated using equation 6 and Equation 8, respectively, and the results are shown in the Table 7-3. All the calculated  $\Delta G_{inject}$  values are negative, which indicates that the conduction band edge of  $TiO_2$  lies, below the excited state of dyes, thus favoring electron injection. The  $\Delta G_{inject}$  of the systems 1-3 increases in the order of D3 (-0.91) < D1 (-0.90) < D2 (-0.80). Therefore, the order of the driving force of systems is D3 > D1 > D2. There is only a slight difference of the LHE for systems 1-3 indicating that all the photosensitizers will give comparable photocurrents. These results indicate that system-3 is the most plausible due to the most negative  $\Delta G_{inject}$  (0.91 eV) and a larger LHE value (0.95), which results in a higher IPCE.

**Table 7-4:**  $\Delta E$  (eV),  $\lambda_{max}$  (nm), ( $f$ ) major transitions dyes anchored to  $TiO_2$

Dyes	$\lambda_{max}$	$\Delta E$	$f$	Major Transitions
D1/ $TiO_2$	493	2.520	0.75	H-3 $\longrightarrow$ L+2 (92.8)
D2/ $TiO_2$	510	2.434	0.80	H $\longrightarrow$ L+1 (95%)
D3/ $TiO_2$	497	2.490	0.86	L $\longrightarrow$ H (96.2)

### 7.3.5. UV-Vis absorption spectra of dyes on the TiO<sub>2</sub> surface

The interface between the sensitizer and TiO<sub>2</sub> plays an important role in the electron injection efficiency. Though (TiO<sub>2</sub>)<sub>n</sub> clusters (n = 4, 6, 8) were simulated, (TiO<sub>2</sub>)<sub>8</sub> containing model was selected because of its balanced electronic properties (conduction band ~ -4.0 eV and band gap 3.18 eV). The models of dyes linked to (TiO<sub>2</sub>)<sub>8</sub> are shown in Fig 7-5, while the simulated UV-Vis spectra of dyes/(TiO<sub>2</sub>)<sub>8</sub> are shown in Fig 7-6. The spectra show a dramatic red-shift when compared to those in solution, with the red shift values of D1/(TiO<sub>2</sub>)<sub>8</sub>, D2/(TiO<sub>2</sub>)<sub>8</sub> and D3/(TiO<sub>2</sub>)<sub>8</sub> are 23, 33 and 25 nm, respectively. This may be due to the increased delocalization of the  $\pi^*$  orbital over the conjugated framework due to the interaction between the carboxylate group and Ti<sup>+4</sup> ions, which decreases the energy of the  $\pi^*$  level. **The band in the UV- region is probably emerging from the transitions of electrons. The major transitions in D1/TiO<sub>2</sub>, D1/TiO<sub>2</sub> and D1/TiO<sub>2</sub> are shown in Fig 7-7.** It can also be observed that dye D2/TiO<sub>2</sub> shows a higher red shift value when compared to other systems. The calculated excitation energies, oscillation strength and  $\lambda_{\text{max}}$ (nm) are shown in Table 7-4.

#### **7.4. Conclusion**

DFT/TD-DFT modeling techniques has been used to conduct the computational study of the geometry and electronic structure of benzene/thiophene based photosensitizers. The calculated results of dyes (D, D2 and D3) are comparable with the experimental data, which shows that hybrid-B1LYP with triple- $\zeta$  (zeta) and SAOP are the right choices in calculating the electronic structure properties and optical properties of dyes respectively. The results also show that LUMO of the dyes is greater than the conduction band of  $\text{TiO}_2$  indicating that a full charge transfer from these dyes to the conduction band of  $\text{TiO}_2$  is thermodynamically allowed. It was also found that the absorption spectra of dyes/ $\text{TiO}_2$  are red shifted owing to the increased delocalization of the  $\pi^*$  orbital of the conjugated framework. Moreover, the calculated results indicate that D3 is the most plausible due to the most negative  $\Delta G_{\text{inject}}$  (0.91 eV) and a larger LHE value (0.95), which results in a higher IPCE. Therefore, it can be concluded from the above study that DFT/TD-DFT is an effective tool to design and computing the optical properties of photosensitizers for solar cell applications

#### **7.5. Acknowledgment**

The authors would like to acknowledge the support provided by King Abdulaziz City for Science and Technology (KACST) through the Science & Technology Unit at King Fahd University of Petroleum & Minerals (KFUPM) for funding this work through the project # 11-ENE1635-04 as part of National Science, Technology and Innovation Plan. KFUPM is also acknowledged for supporting this research. The authors would like to acknowledge the Center of Research Excellence for Renewable Energy at KFUPM for its support.

## **Abstract**

Density functional theory and time dependent density functional theory DFT/TD-DFT modeling techniques are used to conduct a computational study of the geometry and electronic structure of novel oxadiazole based organic sensitizers. A DFT study on the thermodynamic aspects of the charge transport processes associated with dye-sensitized solar cells (DSSCs) suggests that the system with 1,2,4-oxadiazole has a balance among the different crucial factors and may result in the highest incident photon to charge carrier efficiency. The dye/(TiO<sub>2</sub>)<sub>8</sub> anatase clusters were also simulated to illustrate the electron injection efficiency at the interface. This study provides basic understanding of the impact of molecular design on the performance of oxadiazole dyes in DSSCs.

**Keywords:** Density functional theory, oxadiazole, light harvesting efficiency, free energy

## 8.1.Introduction

The world energy demand is continuously increasing and the world power consumption, which is 13 terawatts (TW) currently, is expected to reach about 23 TW by 2050 [1]. Fossil fuels, which are depleting rapidly, meet 80% of the energy requirement of the whole world [2]. Moreover, the burning of fossil fuels raises the amount of carbon dioxide in the atmosphere. Owing to the growing energy demand, exhaustion of oil resources, and global warming issues, there is a need for clean and renewable energy technologies. Among all the renewable energy forms, solar energy has showed its advantages and potential for power generation.[3]The solar radiation from the sun is approximately  $3 \times 10^{24}$  J per year, which is ten times the current energy demand [4]. Therefore, owing to the availability of huge reserves, the conversion of photo energy into electrical energy is generally considered potentially the best way to resolve the world energy crisis.

Inorganic silicon based solar cells are being currently used for the conversion of photo energy on a commercial scale because of their high efficiency [5]. However, the need of highly purified silicon, use of toxic chemicals in their manufacture, and the high cost has restricted their worldwide use. These constraints encouraged the search for low cost and environmentally friendly solar cells. In this context, dye-sensitized solar cells (DSSCs) have received widespread attention in recent years because of their ease of processing and the low cost [6–11]

One of the most important components of the DSSCs is the dye, which absorbs incoming sunlight and produce excitons. The photosensitizer, which is chemically bonded to the porous surface of the semiconductor, can be a metal complex or a metal-free organic

sensitizer. But metal free organic photosensitizers are preferred over ruthenium based sensitizers because of their low cost and good transport properties. The basic structural unit of metal-free dyes is the donor- $\pi$ -spacer-acceptor (D- $\pi$ -A) unit and the photovoltaic properties of such dyes can be fine tuned by selecting suitable groups within the D- $\pi$ -A structure [12].

Many organic groups have been used to tune the electrical and optical properties of light sensitive materials. The best known organic compounds for obtaining such properties are porphyrins [13], styrylarylenes [14], perylenes [15], benzofurans [16], indoles [17], thiazole [18,19] and oxadiazole [20]. Among them, the oxadiazole derivatives are considered the most efficient electron transport materials owing to their good thermal and chemical stabilities and high quantum yield [21]. Many studies have shown that 2-(4-biphenyl)-5-(4-tertbutylphenyl)-(1, 3, 4) oxadiazole exhibits excellent charge transport properties [20,22–25]. Tian and co-workers successfully synthesized the naphthalimide derivatives containing the oxadiazole moiety. They found that oxadiazole moiety increases the electron injection properties and minimizes the carrier recombination [22].

The density functional theory (DFT) and time-dependent DFT (TD-DFT) can provide a deeper understanding of the relationship between molecular structure and properties of compounds. Thus, theoretical calculations are important to design new and efficient dyes for DSSCs [26–33].

Here, the aim is to study the photophysical properties of oxadiazole based organic dyes and establish their structure-performance relationship for application in DSSCs. A series of D- $\pi$ -A oxadiazole based organic dyes that possess different electron-rich fragments or electron-excessive  $\pi$ -bridges were designed. Their electronic properties, absorption

spectra and performances in DSSCs were theoretically studied. This work is expected to provide guidance for experimental synthesis.

## **8.2. Computational Detail**

All the DFT/TD-DFT calculations were executed using Amsterdam Density Functional (ADF) program (2013.01).

### **8.2.1. TiO<sub>2</sub> cluster Model**

BAND mode was used to simulate the anatase TiO<sub>2</sub> cluster. Here, we selected tetragonal anatase crystal structure with single layer (001) surface slab. Then, a 4×1 supercell was created from this slab. All atoms were mapped within the unit cell.

### **8.2.2. Simulation Method**

The ground state geometries of oxadiazole dyes, dye/(TiO<sub>2</sub>)<sub>8</sub> and standard dyes were optimized by applying hybrid Becke,3-parameter, Lee-Yang-Parr (B3LYP) level together with triple- $\zeta$  polarization basis function. The (TiO<sub>2</sub>)<sub>8</sub> nano-particle cluster was also simulated by considering generalized gradient approximation (GGA) at Becke, parameter, Lee-Yang-Parr (BYLP) level with triple- $\zeta$  polarization basis function. UV-Vis spectra of oxadiazole dyes were simulated in ethanol solvent, where the conductor-like screening model (COSMO) was used to take the solvent effects into account[28]. The excitation energies and oscillator strengths for the 80 singlet–singlet transitions at the optimized geometry in the ground state were obtained by TD-DFT calculations using the same basis set as for the ground state and statistical average of orbital potentials (SAOP) model including the solvation effects. In all the calculations, the relativistic effects were taken into account by the zero order regular approximation (ZORA) Hamiltonian in its scalar approximation.

### 8.3.Theoretical background

The performance of DSSCs is evaluated by incident photon to conversion efficiency (IPCE). It is associated with charge collection efficiency ( $\eta_c$ ), electron injection efficiency ( $\Phi_{\text{injc}}$ ) and light harvesting efficiency (LHE), as [27],

$$\text{IPCE} = \text{LHE} \times \Phi_{\text{injc}} \times \eta_c \quad (1)$$

LHE can be calculated as follows [28],

$$\text{LHE} = 1 - 10^{-f} \quad (2)$$

where “ $f$ ” is the absorption of dye associated with the maximum absorption, also called the oscillator strength and  $\Phi_{\text{injc}}$  is related to the free energy of electron injection by [27],

$$\Phi_{\text{injc}} \propto f(-\Delta G^{\text{inject}}) \quad (3)$$

Eq-3 shows that more negative the  $\Delta G^{\text{inject}}$ , the greater the electron injection efficiency. While  $\Delta G^{\text{inject}}$  is the difference between oxidation potential energy of the excited state ( $\text{Eox}^{\text{dye}^*}$ ) and the reduction potential energy of  $\text{TiO}_2$  conduction band (ECB), which can be described as [32]

$$\Delta G^{\text{inject}} = \text{Eox}^{\text{dye}^*} - \text{E}_{\text{CB}} \quad (4)$$

$\text{TiO}_2$  cluster was also simulated and its ECB was found to be -4.01 eV. Similarly,  $\text{Eox}^{\text{dye}^*}$  can be calculated using the following equation [29] ,

$$\text{Eox}^{\text{dye}^*} = \text{Eox}^{\text{dye}} - \Delta E \quad (5)$$

where  $\text{Eox}^{\text{dye}}$  (-HOMO) [30] is the ground state oxidation potential of the dye and  $\Delta E$  is the lowest absorption energy associated with  $\lambda_{\text{max}}$ .

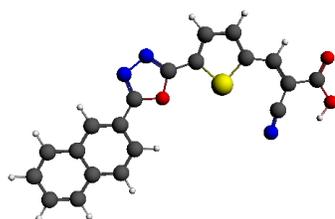

## 8.4. Results and discussion

### 8.4.1. Designed system

The structures and names of new class of dyes are shown in Fig 8-1. In these structures, a naphthalene unit was used as the electron-donating moiety and carboxyl and cyano groups (-COOH and -CN) were introduced as the electron acceptor and the anchor group because of their high electron-withdrawing ability and strong bonding to the semiconductor. Oxadiazole isomers were used as the  $\pi$ -conjugation system, which bridges the donor-acceptor systems. A double bond and a thiophene unit were also introduced to the  $\pi$ -conjugation system to fine tune the planar molecular configuration and to broaden the absorption spectra. The performance of the dyes was tested with different isomers of oxadiazoles as the  $\pi$ -conjugated bridge.

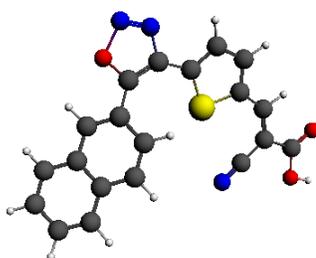

### 8.4.2. Energy levels

The HOMOs, LUMOs, and the band gap energies of the photosensitizers play an important role in providing the thermodynamic driving force for the electron injection. For efficient charge transfer, the LUMOs of dyes must be more negative than the conduction band of the semiconductor while HOMO levels must be more positive than the redox potential of electrolyte. Table 7-1(b) shows the HOMOs, LUMOs, and HOMO-LUMO energy gaps of oxadiazole photosensitizers. The HOMO levels of the systems are in the order of system-4 (-5.827) < system-3 (-5.808) < system-1 (-5.657) < system-2 (-5.582). The LUMO energy levels are in the order of system-1 (-3.956) < system-4 (-3.802) < system-3 (-3.767) < system-2 (-3.625). The insertion of oxadiazole isomers as the  $\pi$ -conjugation unit significantly affects the HOMO and LUMO energy levels. Similarly, the H-L<sub>gap</sub> of systems are in the order of system-1 (1.701) < system-2 (1.957) <

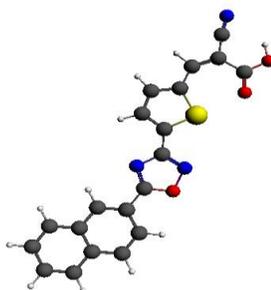

[System-1]

(E)-2-Cyano-3-(5-(5-(naphthalen-2-yl)-1,3,4-oxadiazol-2-yl)-cyanoacrylic acid

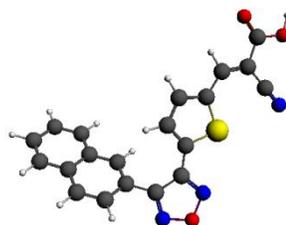

[System-2]

(E)-2-Cyano-3-(5-(5-(naphthalen-2-yl)-1,2,3-oxadiazol-4-yl)-cyanoacrylic acid

[System-3]

(E)-2-Cyano-3-(5-(5-(naphthalen-2-yl)-1,2,4-oxadiazol-3-yl)-cyanoacrylic acid

[System-4]

(E)-2-Cyano-3-(5-(5-(naphthalen-2-yl)-1,2,5-oxadiazol-3-yl)-cyanoacrylic acid

Fig 8-1: Chemical structures of organic dyes

system-4 (2.025) < system-3 (2.041). These results suggest that systems 1-4 should be capable of injecting electrons into the conduction bands of TiO<sub>2</sub>.

**Table 8-1b:** The FMO (eV) and H-L<sub>gap</sub> (eV) energies of systems 1-4

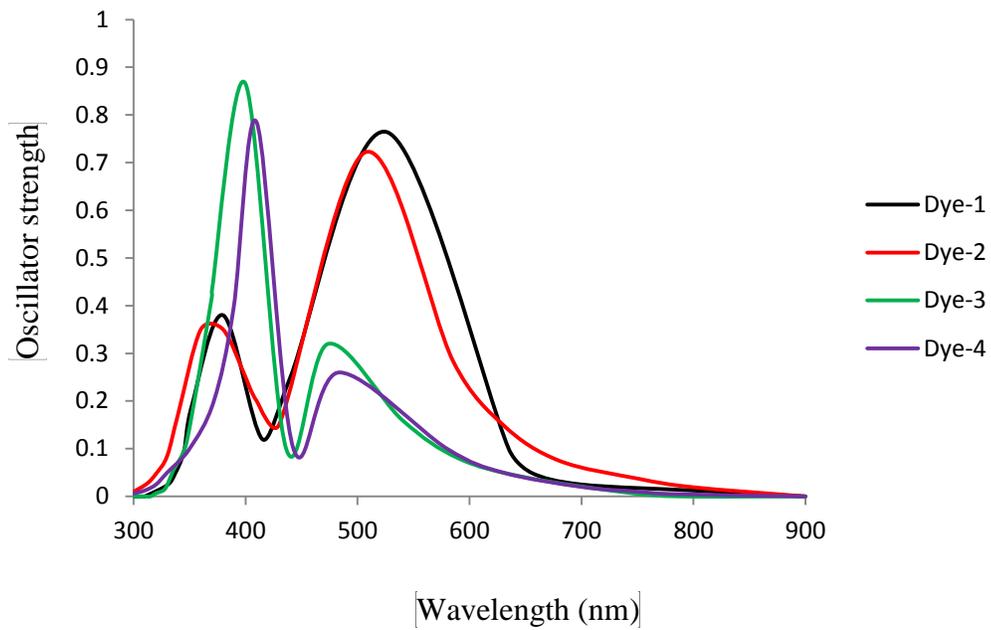

Dyes	LUMO	HOMO	H-L <sub>GAP</sub>
1	-3.956	-5.657	1.701
2	-3.625	-5.582	1.957
3	-3.767	-5.808	2.041
4	-3.802	-5.827	2.025

#### 8.4.3. Absorption spectra of dyes

The simulated absorption spectra of systems 1-4 are shown in Fig 8-2. All the absorption spectra of dyes can be clearly divided into two regions, with the first major peak occurring in the 300-450 nm region and second in the 450-700 nm region. Ground and excited state potential ( $E_{ox}^{dye}$ ), maximum absorption ( $\lambda_{max}$ ), oscillation strength ( $f$ ), and the main transitions are presented in Table 8-2. The main molecular orbitals (MOs) involved in the dominant electron transitions of systems 1-4 are shown in Fig 8-3. The major transitions may be attributed to the transfer of charge from the naphthalene group to -COOH and -CN through the thiophene unit and the  $\pi$ -conjugation system.

**Table 8-2:** Optical, redox and energy levels for oxadizol based photosensitizers

Dyes	$E_{ox}^{dye}$	$E_{ox}^{dye*}$	$\Delta E$	$\lambda_{max}$	$f$	Main Transition
1	5.657	3.296	2.361	525	0.764	H-1 $\longrightarrow$ L (82.4%)
2	5.583	3.133	2.450	507	0.722	H-1 $\longrightarrow$ L (69%)
3	5.808	3.118	2.620	473	0.865	H-1 $\longrightarrow$ L (57%)
4	5.827	3.258	2.569	483	0.780	H-1 $\longrightarrow$ L (68%)

2	520	2.387	0.48
3	492	2.523	0.58
4	495	2.507	0.50

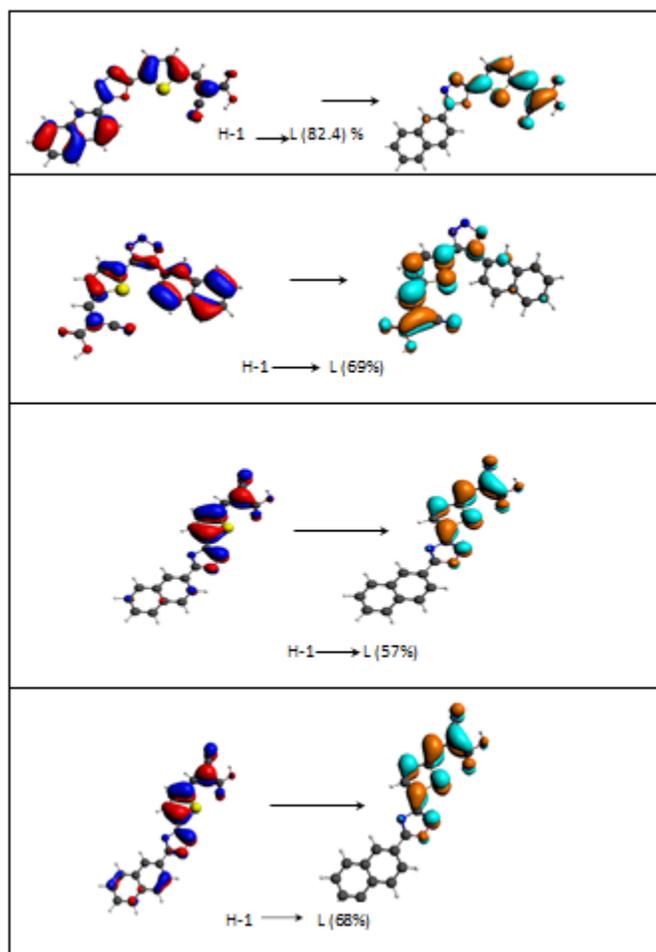

Fig 8-3. Major Transition of system 1-4

#### **8.4.4. UV-Vis absorption spectra of dyes on the TiO<sub>2</sub> surface**

The interface between the sensitizer and TiO<sub>2</sub> plays an important role in the electron injection efficiency. Though (TiO<sub>2</sub>)<sub>n</sub> clusters (n = 4, 6, 8) were simulated, (TiO<sub>2</sub>)<sub>8</sub> containing model was selected because of its balanced electronic properties (conduction band ~ -4.0 eV and band gap 3.18 eV). The models of dyes linked to (TiO<sub>2</sub>)<sub>8</sub> are shown in Fig. 4, while the simulated UV-Vis spectra of dyes/(TiO<sub>2</sub>)<sub>8</sub> are shown in Fig 8-5. The spectra show a red-shift when compared to those in solution, with the red shift values of system 1, system 2, system 3, and system 4 are 17, 13, 19, and 12 nm, respectively. This is due to the fact that the carboxylate group anchored to TiO<sub>2</sub> in which Ti<sup>4+</sup> acts as a proton. The interaction between the carboxylate group and the Ti<sup>4+</sup> ions may lead to the increased delocalization of the π\* orbital. The energy of the π\* level is decreased by this delocalization, which explains the red shift of the absorption spectra. It can also be observed that dye (3)/TiO<sub>2</sub> shows a higher red shift value when compared to other systems. The calculated excitation energies, oscillation strength, λ<sub>max</sub>(nm) and the dominant transitions are shown in Table 8-3.

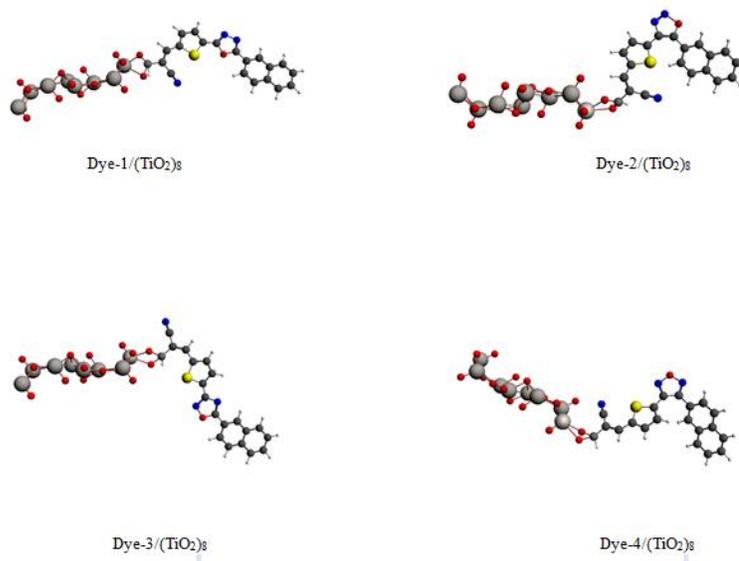

Fig 8-4: The models of system 1-4 with (TiO<sub>2</sub>)<sub>8</sub>

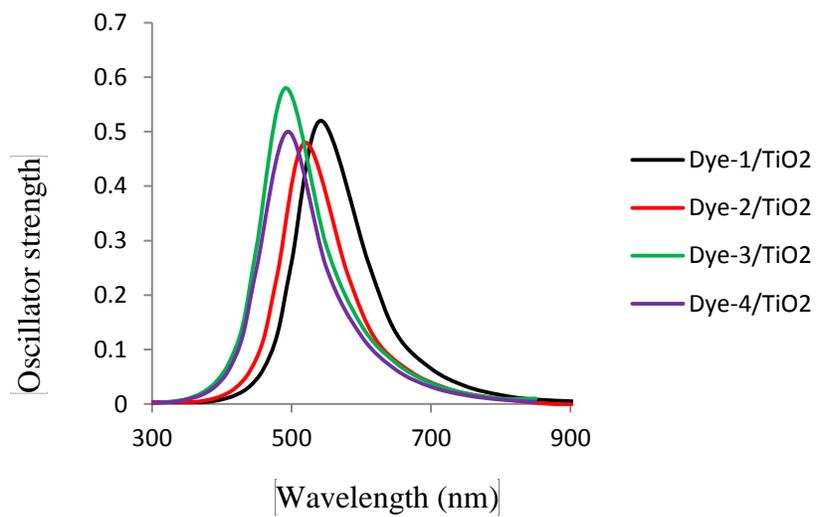

Fig 8-5: Simulated absorption spectra of (TiO<sub>2</sub>)<sub>8</sub>/systems 1-4

#### 8.4.5. Free energy of electron injection and light harvesting efficiency

LHE and  $\Delta G^{\text{inject}}$  can be calculated using Equation 2 and Equation 4, respectively, and the results are shown in Table 8-4. All the calculated  $\Delta G^{\text{inject}}$  values are negative, which indicates that the conduction band edge of  $\text{TiO}_2$  lies, below the excited state of the dyes [28], thus favoring electron injection. The  $\Delta G^{\text{inject}}$  of the systems 1-4 increases in the order of system-3 (-0.882) < system-2 (-0.867) < system-4 (-0.742) < system-1 (-0.704). Therefore, the order of the driving force of the systems is system-3 > system-2 > system-4 > system-1. There is only a slight difference of the LHE for systems 1-4, indicating that all the photosensitizers will give comparable photocurrents. These results indicate that system-3 is the most plausible due to the most negative  $\Delta G^{\text{inject}}$  (0.882 eV) and a larger LHE value (0.86), which results in a higher IPCE.

**Table 8-4:** Free energy of electron injection  $\Delta G^{\text{inject}}$  (eV) and light harvesting efficiency LHE

System	$\Delta G^{\text{inject}}$	LHE
1	-0.704	82
2	-0.867	80
3	-0.882	86
4	-0.742	83

## 8.5. Conclusion

Four photosensitizers with oxadiazole isomers as the pi-conjugated spacer were designed and simulated using DFT/TD-DFT. The UV-Vis spectra as well as the driving force ( $\Delta G^{\text{inject}}$ ) of the systems 1-4 show that these dyes are potentially good photosensitizers. The results show that LUMO of the dyes is greater than the conduction band of  $\text{TiO}_2$  indicating that a full charge transfer from these dyes into the conduction band of  $\text{TiO}_2$  is thermodynamically allowed. It was also found that the absorption spectra of system-1 to system-4 are red shifted owing to the increased delocalization of the  $\pi^*$  orbital of the conjugated framework. Moreover, there is no significant difference between the LHE of systems 1-4. Therefore, it can be concluded that system-3 with 1,2,4-oxadiazol shows a balance among the different crucial parameters and is expected to be a promising sensitizer in the DSSC field.

## 8.6. Acknowledgment

The authors would like to acknowledge the support provided by King Abdulaziz City for Science and Technology (KACST) through the Science & Technology Unit at King Fahd University of Petroleum & Minerals (KFUPM) for funding this work through project # 11-ENE1635-04 as part of the National Science, Technology and Innovation Plan. KFUPM is also acknowledged for supporting this research. The authors would like to acknowledge the Center of Research Excellence for Renewable Energy at KFUPM for its support.

## CHAPTER 9

### CONCLUSIONS & RECOMMENDATIONS

#### 9.1. Conclusion

Narrow absorption spectra and/or low absorption intensity of the sensitizers and the recombination of injected electrons with the electrolyte are the two major causes of the low conversion efficiency of DSSCs. In this work, the co-sensitization strategy was applied to obtain the broader and a more intense absorption band. While hybrid composites of MWCNTs and graphene micro-platelets with  $\text{TiO}_2$  were used to reduce the dark current.

The mixed solution of N719 and N3 in methanol was used for the co-sensitization of the photoanodes of DSSCs. More intense and broader absorption spectrum of the co-sensitized  $\text{TiO}_2$  film was observed than the absorption spectra of the individual N719 and N<sub>3</sub> dyes. This is because the CNTs may exhibit photosensitizing properties, thus extending photovoltaic properties into the visible spectrum. The results indicate that the power conversion efficiency of DSSC based on 0.4N719+0.1N<sub>3</sub> is 17% and 11% higher than based on the individual dyes N719 and N<sub>3</sub> respectively. Moreover, the cell efficiency of the DSSC with a molar ratio of N<sub>3</sub>/N719 = 0.1/0.4 was further improved to 4.46% by the incorporation of MWCNTs in  $\text{TiO}_2$ . Optimum concentration (0.04%) of CNTs in photoanode does not affect the transparency of  $\text{TiO}_2$  layer, while significantly increases the PCE of DSSC.

It has been observed that the enhancement of PCE due to CNTs is limited by poor contact between CNTs and TiO<sub>2</sub>. Two dimensional Graphene nano carbon material was also introduced to prepare the hybrid film. The incorporation of graphene in TiO<sub>2</sub> slowing the recombination of photogenerated electrons, extending the excitation wavelength and increasing the surface-adsorbed amount of dye. It was examined that the dispersion of small amount of graphene in TiO<sub>2</sub> can significantly improve the photo conversion efficiency of DSSCs. Optimum concentration (0.09%) of graphene in photoanode does not affect the transparency of TiO<sub>2</sub> layer, while significantly increases the PCE of DSSC, with a maximum value of 4.12%.

DFT and time dependent TD-DFT were also employed to investigate the thermodynamic aspects of charge transport processes involved in DSSCs. Hybrid functions with triple- $\zeta$  polarization basis function were employed to simulate the geometries of sensitizers. While, UV-Vis spectra of sensitizers and dye anchored to TiO<sub>2</sub> were simulated in different solvents. The conductor-like screening model (COSMO) was selected to take the solvent effects into account. The excitation energies were examined using TD-DFT and statistical average of orbital potentials (SAOP) model including the solvation effects. The simulated results were in good agreement with the experimental values. Thus, hybrid functions with triple- $\zeta$  polarization basis function and COSMO solvation model with SOAP function were appropriate for computing the HOMOs, LUMOs, band gap, free energy of electron injection, absorption spectra and LHE of photosensitizers.

The output of our research work is ten publications, four of them have been accepted and six are under review. We also have also filed two patents. The detail of manuscripts and patents are

Improving the efficiency of Dye sensitized solar cells by TiO<sub>2</sub> – graphene nanocomposite photoanode, Journal of Nanomaterials (Under Review)

## Patents

1. Oxadiazole based photosensitizers for dye-sensitized solar cells ([US14/720287](#))
2. Organic dyes incorporating the oxadiazole moiety for efficient dye-sensitized solar cells ([US14/718040](#))

## 9.2. Recommendations

Low efficiency and low stability are the major challenges for the commercial growth of DSSCs. The following factors are responsible for the low efficiency and stability of DSSCs,

- 1) Non-optimized dark current
- 2) Poor performance of dyes in the NIR region
- 3) Poor contact between the electrodes
- 4) High volatility and high viscosity of electrolytes
- 5) Degradation of electrolyte properties due to UV absorption of light

Following steps can be recommended in order to further enhance the efficiency and stability of DSSCs,

- 1) Improvement in the morphology of semiconductors to reduce dark current
- 2) Improvement in the dye design to absorb light NIR region
- 3) Develop low volatile and less viscous electrolyte to improve the charge transfer rate.
- 4) Improvement in mechanical contact or adhesion between the two electrodes
- 5) Use of additives for dyes and electrolytes that enhance their properties.

# Curriculum Vitae

## Umer Mehmood

Department of Chemical Engineering,  
King Fahd University of Petroleum & Minerals,  
Dhahran, Kingdom of Saudi Arabia

Phone (M): +966 532432097

Phone (M): +92 3324707967

Nationality: Pakistani

Date of birth: 06-09-1984

Email: organicchemistry2@gmail.com

## EDUCATION

**Ph.D** : Chemical Engineering, 2011-2015

King Fahd University of Petroleum & Minerals, Saudi Arabia

**Thesis:** Synthesis and Characterization of Dye Sensitized Materials for Solar Cell Applications

**M.Sc** : Polymer Engineering (First position holder in department), 2009-2011

University of Engineering & Technology, Lahore, Pakistan

**Thesis:** Recycling of mixed plastics waste

**B.Sc.:** Chemical Engineering (Polymer) (Third position holder in department), 2004-2008

University of Engineering & Technology, Lahore, Pakistan

## RESEARCH INTERESTS

- Solar cells
- Conductive polymers
- Quantum Mechanical Modeling (DFT/TD-DFT)
- Process Simulation

## **TEACHING INTERESTS**

- Transport Phenomena
- Heat Transfer
- Reaction Engineering
- Mass Transfer
- Polymer Material Testing and Characterization

## **WORK EXPERIENCE**

**King Fahd University of Petroleum & Minerals, Saudi Arabia**  
**Lecturer-B      Sep 2011-Present**

- Teach Chemical Engineering Laboratory (CHE-409) to undergraduate students for two years
- Teach Chemical Engineering Laboratory (CHE-309) to undergraduate students for one year
- Write technical reports for the projects to be submitted to King Abdulaziz City for Science and Technology (KACST)
- Work on the development of dye sensitized solar cells as part of my PhD thesis
- Teaching assistant in various undergraduate courses

**University of Engineering & Technology, Lahore, Pakistan**  
**Lecturer                  June 2009-Sep 2011**

- Taught Various undergraduate courses, which include
  - ✓ Transport Phenomena
  - ✓ Heat Transfer
  - ✓ Mass Transfer
  - ✓ Reaction Engineering
- Testing of polymer materials
- Involved in developing different laboratories

## **INTERSHIPS and TRAINING**

- BASF, Pakistan (4 weeks)
- Engro Poymer (1 week)
- Sui Northern Gas Pipelines Limited, Pakistan (4 weeks)

## **COMPUTER SKILLS**

- MATLAB
- ADF (Amsterdam Density Functional program)
- Aspen HYSYS
- Aspen Plus
- MS office

## **LANGUAGE SKILLS**

- English-Excellent oral and written skills
- Urdu-Excellent oral and written skills

## **JOURNAL PUBLICATIONS**
